When you right-click in the **Current Selections** window without having highlighted a field, the float menu that contains the following commands is displayed:

- **Clear All Selections:** Deselects all the selected values of the document.
- **Lock All Selections:** Locks all the selected values of the document.
- **Unlock All Selections:** Unlocks all the locked values of the document.
- **Data:** Copies the name(s) of all the selected value(s) of the document, as well as the name(s) of the field(s) in which the selections were made, to the clipboard.

The **Current Selections** window resembles a sheet object in the way that it is sizable and can be kept open while working with a document. It will be left open when you close the current QlikView document, and its contents will change if you open another document. Just as the sheet objects, it is dynamically updated as soon as new selections are made, which gives you an overview of the current selections at any time.

The maximum number of distinct selected values to be shown in the **Current Selections** windows is specified in the **User Preferences** dialog. When more values are selected, they will only be displayed as 'x values of y' for the respective field.

Selections made in AND-boxes are preceded by & or !, depending on whether it is a selection or an exclusion.

If you select in a field by using search, the search string is displayed as the field value.

8.15 Selections in Other Objects

You can make selections directly in fields in most objects. In tables, the color of the cell becomes green to mark its value as selected. Click to select a value or paint with the mouse to select multiple values.

You can also make selections by searching.

The following section describes how you can make selections in the different types of objects. If you find that you cannot make selections in an object as described below, the chart may be in **Detached** mode or **Read Only** mode.

Statistics Boxes

In statistics boxes you can click on some of the statistical quantities such as **Min**, **Max** and **Median**, and the corresponding value will be selected. The selection is not marked in the statistics box but only in other boxes.

Multi Boxes

A row in the Multi Box represents a field. Clicking on the small arrow displays a list of values that belong to the field. You can make selections and searches in this list just as in a list box.

Table Boxes

You can make selections in table boxes by clicking in any cell or by painting over an area covering one or more rows and one or more columns. If the option **Drop-down Select** is active, an arrow is displayed in the column heading. Clicking on the arrow displays a list of the values that belong to this field. You can make selections and searches in this list just as in a list box.

Slider/Calendar Objects

In sliders, where a single field is the basis, you can select a value by adjusting the thumb tack to the desired position. If the slider is accordingly configured, the size of the thumb tack can be changed with a mouse click. This way it is possible to select several values.

Clicking on the small calendar symbol in a calendar object opens the calendar. You can select a date or a period of time with the mouse depending on the configuration of the calendar object, and this selection is transferred to the underlying field. Using Ctrl+Click you can select several periods even if they are in different months or years.

Bar, Line, Combo, Radar, Grid and Scatter Charts

In these objects, you can make selections in different ways:

- By clicking on a single data point or painting over several data points inside the plot area. When painting, the area covered is shown with a green raster. The selection will be made for the

dimension values used to calculate the selected data point(s).

- By clicking or painting in the chart legend (except when the legend is indicating chart expressions rather than dimension values).
- By clicking or painting over the dimension axes and its labels (except scatter charts). The corresponding field values will be selected.
- By painting over the expression axes and its labels. The field values which generate data points in the indicated result area will be selected.

When painting selections in line charts and bar charts with more than one dimension the behavior of the QlikView selection logic differs slightly from that of other charts in order to better reflect the expectations of the user. Selections in these types of charts do not affect both dimensions at the same time.

In line charts selections will be primarily done in the second dimension. This means that painting over a line will select the entire line over all x-axis dimension values.

In bar charts the opposite applies. Selections primarily apply to the first dimension. This means e.g. that clicking one bar segment will result in a selection of that segment's x-axis dimension value but leave all stack or cluster segments possible. When selections have narrowed down the primary selection dimension to one single value, the old selection logic will apply again, making selections prevail also in the secondary selection dimension.

In combo charts selections always affect all dimensions.

Pie Charts

You can make selections inside the plot area by clicking on a single pie slice or painting over several slices. When painting, the area covered is shown with a green raster. The selection will be made for the dimension values used to calculate the selected data point(s).

You can also make selections by clicking or painting in the chart legend.

Block Charts

You can select individual blocks in block charts. The drilldown functionality is used to refer to a certain dimension - selecting the first block refers to the first dimension, selecting a second block within the first refers to the second dimension etc.

You can also select several blocks by painting an area. This selected area is marked green until you release the mouse button. Such a selection refers back to the value or values of the first dimension. Based on these values the corresponding blocks are calculated. If a selection crosses the block borders of several values that belong to the first dimension, it will affect all related values belonging to the second and third dimensions as well, not only those in the selected area.

Gauge charts

Selections cannot be made in gauge charts since there is no dimension defined.

Straight Tables

You can make selections in the dimension columns of a straight table by clicking on a cell or painting over several cells. The selected area is marked green until you release the mouse button.

If **Drop-down Select** is activated in a column that represents a dimension, a small arrow will be displayed in the column header. Clicking on the arrow will display a list of all values of the field. You can make selections and searches in this list.

You can also make selections in the expression columns by clicking in a single cell. The selection will be made for the dimension values used to calculate the selected expression cell.

Pivot Tables

You can make selections in a pivot table in the dimension columns/rows by clicking on a single cell. The selected cell is marked green until you release the mouse button.

If **Drop-down Select** is activated in a column that represents a dimension, a small arrow will be displayed in the column header. Clicking on the arrow will display a list of all values of the field. You can make selections and searches in this list.

You can also make selections in the expression columns/rows by clicking in a single cell. The selection will be made for the dimension values used to calculate the selected expression cell.

8.16 Search

As an alternative to making selections by clicking values in QlikView objects, you can make selections through text or numeric search.

Making Selections Using Search

The following section describes how to make selections using text search, and how QlikView responds to different commands. Perform the following steps:

1. Click on the list box caption, and type the search string. The string is not case sensitive. The search string appears in the pop-up search box. As a result, QlikView will display all the values of the selected field that fulfill the criteria of the search string.
2. Press Enter or click one of the cells in the result to select that value.

If you press Ctrl + Enter, all values matching the search string are added to your selections, as long as they are not already included in previous selections. Values matching the search string but already included in previous selections are excluded from any selection when pressing Ctrl + Enter. Values included in previous selections and that don't match with the search string are retained in your selection.

The search box is automatically closed when you press Enter, Esc, or when you click in the layout. You can also close the search box by clicking the x icon in the search box. The search box is sizable and will retain its size when it is opened again.

Search in Multiple List Boxes

All active list boxes will be included in the search. To search in multiple list boxes, Shift-click on their captions to make them active. It is not possible to select the resulting values by pressing Enter when searching in multiple list boxes.

If a selection has already been made, there are two ways in which a search can be interpreted:

- Search only among the optional values
- Search among all values, i.e. including the excluded values in the search

To set the search mode to work in, it is possible to either select or deselect **Include Excluded Values in Search** in the **User Preferences** dialog. This mode can also be set on certain individual sheet objects.

If the logical AND-option is set for a field, it may not be possible to select multiple values found.

Text Search

The simplest way of searching is text search. QlikView will search for field values matching a text string that you type.

In normal search (no wildcards are used), QlikView will look for words that begin in the same way as the search string. If the search string contains several words separated by blanks, QlikView will interpret it as several search strings and display field values that contain either of the strings.

Wildcards

You can use one or several wildcards in a search string. The following wildcards can be used:

Search wildcards

Wildcard	Representation
*	Zero or more characters, including blank. This wildcard is flexible and matches any character or any block of characters in a specific position.
?	A single character, including blank. This wildcard is useful when you suspect that a string may be misspelled, when you are unsure of the spelling, or when the string contains special characters that may be difficult to reproduce correctly.
^	Beginning of word within field value. This wildcard is used in conjunction with other wildcards.

*If you use wildcards, only those records that match the entire search string are displayed, that is, a blank does not imply a logical OR. The search string '*creamed' does not get a match on 'Rocky's creamed corn' since the value does not end with 'creamed'. Neither does 'creamed*' result in a match on 'Rocky's creamed corn', since the value does not start with 'creamed'.*

Wildcard examples

Example	Result
a*	Finds all values that begin with the letter “a”, including strings with several words where the first word begins with an “a”.
*b	Finds all values that end with the letter “b”, including strings with several words where the last word ends with a “b”.
c	Finds all values that contain the letter “c”, including strings with several words
^ab	Returns all values that have words that begin with “ab”. Equivalent to a normal search for “ab”, but unlike the normal search it can be made more complex using wildcards. It can also be used in a programmatic search, such as in Set Analysis.
r?ck	Finds all values that have four letters and start with an “r”, followed by any character, and ending with “ck”, for example, “rack”, “rick”, “rock”, and “ruck”.
r?? ?????d	Finds all values that consist of a three-letter word beginning with an “r” and a five-letter word ending with a “d”.

*Space in a search string makes a difference. If you search for “*corn” you get matches on strings ending with, for example, “popcorn” as well as “corn”. If you use a space in your search string, “* corn”, you only get matches that end with “corn”.*

Fuzzy Search

Fuzzy search is similar to standard search, with the exception that it compares and sorts all field values according to their degree of resemblance to the search string. Fuzzy search is especially useful in situations where misspelling is an issue. It can also help you find multiple values that are nearly identical to each other.

When a fuzzy search is made, a tilde-character (~) is displayed in front of the search string.

If starting a text search with a tilde-character, the text search window will open in fuzzy search mode. The search window will contain the tilde with the cursor placed after it. As you type, all values will be sorted by the degree of resemblance to the search string with the best matches at the top of the list. If you press Enter, the first value in the list will be selected.

Numeric Search

You can make selections using numeric search as well. This is very similar to text search. The only difference is that the search string must begin with one of the following relational operators:

Numeric search operators

Operator	Description
>	greater than
>=	greater than or equal
<	less than
<=	less than or equal

Examples:

Numeric search operator examples

Example	Result
>900	will find all values greater than 900
<=900	will find all values less than or equal to 900
>900<1000	will find all values greater than 900 and less than 1000
<900>1000	will find all values less than 900 or greater than 1000

Initial Search Mode

When starting to type text, the behavior may differ: in some cases, QlikView adds wildcards to the search string, to facilitate a wildcard search.

The preferred search mode can be set in the object properties and in **User Preferences**.

Search String Evaluation

After a search string has been entered or edited, QlikView evaluates which one of the above described search behaviors to select.

If the search string contains wildcard characters, a wildcard search will be made instead of normal search.

It is always possible to change the search mode simply by deleting or adding wild cards, a greater than (>) or smaller than (<) symbol in the search string.

Associative Search

The list box's search box contains a chevron (>>) to the right. If you click it, the search box is expanded to the right and a secondary result set is displayed next to the primary result set. This secondary list contains search matches in other fields. It is now possible to click in the secondary result set and make temporary selections. Such selections will narrow down the result in the primary result set. Once you make a selection in the secondary list, you can enter a new search string before making the selection in the primary list. Finally, when you make a selection in the primary result set, the secondary result list is closed.

Advanced Search

For complex search expressions it is possible to use the **Advanced Search** dialog, which can be invoked by the keyboard shortcut Ctrl+Shift+F. If you start your text search with an equal sign (=), you may enter an advanced search expression involving search criteria for associated fields and full boolean logic. After the equal sign you can type any valid QlikView layout expression (*Edit Expression Dialog (page 113)*). The expression will be evaluated for each field value in the search field. All values for which the search expression returns a non-zero value will be selected.

Example:

=MyField like 'A*' or MyField like '*Z'

if e.g. invoked from a list box containing the field MyField, the search would return all field values either starting with the letter A or ending with the letter Z.

Example:

=sum(Sales)>sum(Budget)

if e.g. invoked from a list box containing the field Salesman, the search would return all salesmen with an associated sales value larger than their associated Budget.

Text Search Box

In this text box the search string of a free text search is shown. The string can be edited.

Advanced Search

If you start your text search with an equal sign = , you may enter an advanced search expression involving search criteria for associated fields and full boolean logic. After the equal sign you may type any valid QlikView layout expression. The expression will be evaluated for each filed value in the search field. All values for which the search expression returns a non-zero value will be selected.

Examples:

Advanced Search examples

Example	Description
=MyField like 'A*' or MyField like '*Z'	if e.g. invoked from a list box containing the field MyField , the search would return all field values either starting with the letter A or ending with the letter Z.
=sum (Sales)>sum (Budget)	if e.g. invoked from a list box containing the field Salesman, the search would return all salesmen with an associated sales value larger than their associated Budget.

8.17 Advanced Search dialog

The **Advanced Search** dialog provides a convenient way of formulating complex search queries to be applied on QlikView fields. Unlike the standard search box that appears when starting a search by typing when a list box is active, the result of the search is not interactively visible in the layout until submitting the search by pressing the **Go** button. The dialog can be kept open while working in the QlikView layout. The dialog is fully sizeable in order to facilitate editing of large and complex expressions.

Search dialog elements

Element	Description
Search in	The field in which the search will be made. When entering the dialog it will be set to the field of the active list box. It is possible to change search fields by using the drop-down at any time.
Search Expression	This is where the search expression is typed. The same rules apply as when using the normal search box.
Go	Applies the search to the search field
Back	QlikView remembers the last 100 selections. Click this button to go one step back in the list of selections.
Forward	Click this button to go one step forward in the list of selections (equivalent to canceling the last Back command). This only possible if the Back command has been used immediately before.
Clear Field	Clears selections in the current search field.
Clear All	Clears all selections in the document
Help	Opens the Help dialog for advanced search.
Close	Closes the dialog.

The the pane with three tabs at the bottom of the dialog can help you when you build advanced search expressions.

Fields

Select the **Fields** tab to access controls for pasting syntax relating to QlikView field data.

Field tab elements

Element	Details
Aggregation	In this drop-down it is possible to choose from the statistical aggregation functions available in the QlikView layout.
Table	In this drop-down it is possible to select a specific table from which to pick fields in order to make navigation in the Field drop-down easier.

Element	Details
Field	This drop-down lists all the fields available. The list may be narrowed down by selecting a specific table in the Table drop-down above.
Show System Fields	If this check box is marked, the list containing the fields of the document includes the system fields.
Distinct	The statistical functions are by default calculated on the number of occurrences in the original table. Sometimes, however, duplicates are not to be calculated. If this is the case, mark this check box before pasting the function.
Paste	Pastes the selected function or just the field into the Search Expression edit box. A percentage can be given when using the fractile function.

Functions

Select the **Functions** tab to access the controls for pasting syntax relating to QlikView general functions.

Functions tab elements

Element	Details
Function Category	In the drop-down it is possible to select a category of functions in order to make navigation in the Function Name drop-down easier.
Function name	In the drop-down it is possible to select a function for pasting into the expression out of all functions available in the QlikView layout. The list can be reduced to show only functions belonging to a certain category by means of a selection in the Function Category drop-down above.
Paste	Pastes the selected function name into the Search Expression edit box.

At the bottom of the dialog there is a pane showing the argument syntax of the function selected in the **Function Name** drop-down.

Variables

Select the **Variables** tab to access the controls for pasting syntax relating to QlikView variables.

Variable tab element

Element	Details
Variables	In the drop-down all currently defined variables in the document are found.
Paste	Pastes the selected function into the Search Expression edit box.
Show System Variables	If this check box is marked, the list in the Variables drop-down will include the system variables.

At the bottom of the dialog there is a pane showing the current value of any variable selected in the **Variables** drop-down.

8.18 AND-mode in List Boxes

When multiple selections are made in a list box set to AND-mode, only data associated to all of the selected field values will be shown in the other fields.

Example:

Your data source contains information about which customers have purchased different articles.

When you select a couple of articles in the default mode, QlikView will show you the customers that have purchased any of the selected articles.

When you select a couple of articles in AND-mode, QlikView will show you the customers that have purchased all of the selected articles.

AND-Mode Prerequisites

The mode for the field is set in **List Box Properties: General** tab.

When **And mode** is activated, an ampersand ("&") will be displayed in front of selected values.

If clicking and holding a value for a moment, the selection will switch from (**AND**) selected (green) to **NOT** selected (red). The ampersand will also be replaced by an exclamation mark ("!"). The **NOT** selection which is a forced exclusion of the value or values so marked, can only be made when a list box is in **And mode**.

AND-Mode criteria

A field cannot always be set to logical AND-mode. The reason for this is that the and alternative is logically meaningful only if the concerned field is linked to only one other field. The following criteria must be fulfilled:

- the field must only exist in one logical table,
- the field must be the second column of no more than two columns,
- the table must not contain any duplicate records, and
- the field must be loaded with the distinct qualifier. If the table is loaded using a select statement, you must use a preceding load distinct *.

Setting a List Box in AND-Mode

The following procedure describes how to set a list box in AND-mode instead of the default mode (logical OR). Perform the following steps:

1. Make sure that the AND-mode criteria are fulfilled.
2. Right-click on the list box and select **Properties**.
3. On the **General** tab, mark the **And mode** check box.

Forced Exclusion

Forced exclusion (sometimes referred to as NOT-selection) is closely related to the AND-selection. The forced exclusion makes it possible to explicitly exclude a field value, which means that the solutions found by QlikView may not be associated with the excluded value.

The forced exclusion is made by clicking a cell and keeping the mouse button pressed until the cell turns red. Ctrl-clicking in this manner is equivalent to an exclusion that is an additional requirement to the previous selections/ exclusions. The forced exclusion can only be made on a field that is in AND-mode.

If you want to force the exclusion of specific field values in objects such as text objects, you have to modify the script syntax. For example, if your script statement is the following:

```
=count({<ANDActor=>}DISTINCT Title)
```

Modify it as follows:

```
=count({<~ANDActor=, ANDActor=>} DISTINCT Title)
```

8.19 Alternate States

Description

You can use **Alternate States** to perform comparative analysis between sets of multiple data items, for example for basket analysis purposes. A state holds a set of selections.

The QlikView developer can create multiple states within a QlikView document and apply these states to specific objects within the document. The end-user can create copies of these objects (server objects) and then put those objects into different states.

The most important difference between **Detach** and **Alternate States** is that ALL objects in a given state will respond to user selections made in that state. Objects in a given state are not affected by user selections in the other states.

Alternate States functionality is not accessible in the load script.

*Alternate States functionality is enabled by a QlikView developer and should be used with caution as it can cause great confusion with end-users as there is no automatic on-screen indication that objects or expressions are in, or reference, alternate states. It is up to the QlikView developer to provide this information to the end-user using the **StateName()** function.*

Visualization of an Alternate State selection might fail if the data is under Section Access or data reduction. An Alternate State selection cannot be visualized if the data is not accessible by the users consuming the QlikView document under section access.

Setting Alternate States

Do the following to enable and set alternate states:

1. Click **Alternate States...** in the **Document Properties: General** tab.
The **Alternate States** dialog opens.
2. Click **Add...** to create a number of states, and name them. The names will be referred to as state identifiers.
3. Click **OK** to close the dialog.

Now the QlikView developer can create new Alternate States from within screen objects.

End-users who access QlikView documents from a QlikView Server can make use of Alternate States but cannot create Alternate States.

Assigning States to Objects

Do the following to assign a state to an object:

1. Open the **Properties** dialog and select the **General** tab.
2. Set **Alternate State** to the state identifier you want to use for the object.

The object will now be independent from the rest of the document in terms of selection, unless other objects are set to the same state.

There are two states that are always available; **default state** and **inherited**. The **default state** is the state where most QlikView usage occurs and is represented by \$. The QlikView document is always in the **default state**. Objects can inherit states from higher level objects, such as sheets and containers. This means that states are inherited as such: Document - Sheet - Sheet Objects. The sheets and sheet objects are always in the **inherited** state unless overridden by the QlikView developer.

Comparing Alternate States

You can compare two states on the same object. For example, you can create a line chart to display both states of the data with the same axis by assigning a state in the expression using set analysis.

Example:

If you have defined the states *Group1* and *Group2*, you can compare the average of field *Adj.Close* for the groups by showing these two expressions in a line chart:

```
Avg({[Group1]} [Adj.Close])
```

```
Avg({[Group2]} [Adj.Close])
```

Logical Behavior when Using Alternate States

Pressing the **Clear** button affects all states.

In the Inter Explorer plugin, a menu item has been added to the **Clear** button drop-down menu that allows a user clear the selections of a specific state. This menu is not available in the Ajax client, but the same function can be achieved by creating an action button connected to the Clear action with a specific state.

Pressing the **Back** and **Forward** buttons affects all states. There is no mechanism to move back and forward through specific states.

Pressing the **Lock** and **Unlock** buttons affects all states. It is not possible to lock and unlock specific states with these buttons. It is possible to lock specific fields in states by using the right-click menu on list boxes in a specific state.

The menu items in the **Selections** menu apply to all states. There is no mechanism to affect specific states in this menu.

Alternate States can be used with linked objects. The state applies to all instances of an object. Changing a state on a linked object will put the other linked objects into the same state.

Triggers fire in all states.

Actions can be set to occur in specific states. One known exception is the **Run Macro** action. It can be set to run in a specific state; however macros fire in all states.

Objects that make use of a missing state (the state was removed by a developer) will revert to the default state though the **Alternate State** drop-down, that will display information such as:

AlternateStateName <unavailable>.

You can only use field functions with a State argument in conjunction with Alternate States.

Variables in Alternate States

You can specify which state to use when expanding a variable. Changes in a specific state do not affect variable values that are expanded in another state. If you do not specify a state, the variable is expanded in the default state.

Example:

If you have a state named `myState`, and a variable named `vmYvar`:

- `$(vmYvar)` expands the variable in the default state.
- `${{myState} vmYvar}` expands the variable in the `myState` state.

8.20 Bookmarks

The current state of selections can be saved as bookmarks for later use. Bookmarks capture selections in all states defined in a QlikView document. When recalling a bookmark, the selections in all states will be applied.

Bookmark types

There are different types of bookmarks:

- **Document bookmarks:** are stored inside the QlikView document. They will always be available to whoever opens the document locally or from a QlikView Server.
- **User bookmarks:** are stored separately on the user's computer. They will only be available to the user who created them on the computer where they were created. If the document is moved or renamed all personal bookmarks related to it will be lost.
- **Personal Server bookmarks:** are only available when working with a document on QlikView Server and only to authenticated users. They are stored in a repository on the server and are accessible to the user from any computer where authenticated.
- **Shared Server bookmarks:** are only available when working with a document on QlikView Server and only to authenticated users. Any user who has created a personal server bookmark may flag this as shared to other users. They will then become available to other users. Just like personal server bookmarks shared server bookmarks are stored in a repository on the server.
- **Temporary bookmarks:** are created by QlikView when some functions are used, such as **Mail with Bookmark as Link** and document chaining. They are only available when working with a document on QlikView Server and only to authenticated users.

*If you make changes to the data model, existing bookmarks may stop working, even if you retain the same field names. For example, enabling the **Always One Selected Value** option in the **List Boxes** properties.*

Add Bookmark dialog

The current state of selections can be saved as a bookmark by choosing **Add Bookmark** from the **Bookmarks** menu or by pressing Ctrl+B. Bookmarks can also be created via bookmark objects in the QlikView layout. Doing this will cause the **Add Bookmarks** dialog to appear.

The dialog looks slightly different depending on whether it is a local document or a document on QlikView Server that the user is working with. We start by describing the dialog for local documents, and then describe the differences for server documents.

Bookmark fields

Field	Details
Bookmark Name	The default name for the created bookmark is that of the current date. In addition, the first bookmark created on a specific day gets number 1, the second number 2, etc. However, it is possible to change the default name to a more explanatory text by entering an optional name.
Make this bookmark a document bookmark	By marking the check box, the bookmark will be saved with the document. This option is available for local documents only. If the check box is not marked, the bookmark will be created as a user bookmark, stored locally on the computer.
Include Selections in Bookmark	By marking the check box the bookmark will include the selections made in the application.

Field	Details
Make bookmark apply on top of current selection	By marking the check box, the bookmark will be applied without first clearing existing selections in the document.
Include Layout State	By marking the check box, the bookmark will store the layout state of all sheet objects on the active sheet at the time of the bookmark's creation. This includes, for example, the cycling position of a chart. When recalling a bookmark with layout information, QlikView will attempt to activate the sheet and restore sheet objects to that state. The layout state in bookmarks includes only show state (minimized/maximized) and expansion state, not the entire property of the object. Layout of all straight tables and pivot tables on the active sheet will be preserved, unless they are located inside container objects. However, straight tables and pivot table column positions will not be preserved. There is no reset option for straight tables and pivot table layout. A workaround would be to create a document bookmark in the document clear state with the original layout of the pivot table.
Include Scroll Positions	Marking this check box will include the current vertical scroll position in table objects in the bookmark.
Include Input Field Values	By marking this check box, the values in input fields will be stored in the bookmark.
Info Text	In the edit box it is possible to enter a text describing the bookmark or a message to be shown when recalling the bookmark.
Popup Message	If the check box is marked, the bookmark info text (if it exists) will be displayed in a pop-up window each time the bookmark is recalled.

Differences for server documents

Field	Details
Create as a server bookmark	When this check box is marked, the bookmark will be created as a personal server bookmark, stored in a repository on the server. This option is available only if the user is an authenticated user and provided that the QlikView Server and the document owner allows the creation of server bookmarks. If the check box is not marked, the bookmark will be created as a user bookmark, stored locally on the computer.
Share Bookmark with Others	Provided that a personal server bookmark is created, marking this check box will immediately share the bookmark for use by other authenticated users of the same server document. It is possible at any time revoke the sharing by deselecting the Share check box in the My Server Bookmarks page of the Bookmarks dialog.

Sort order is not saved in the bookmark. It will be replaced by the sort order defined in **Properties** when you select a bookmark.

Remove Bookmark

Opens a cascade menu where the first ten document bookmarks are listed above the first ten personal bookmarks defined for the active document. Selecting a bookmark deletes it.

Bookmarks dialog

The **Bookmarks** dialog can be opened by clicking **More...** in the **Bookmarks** menu. It is divided into two tabs (local documents) or five tabs (server documents), one for document bookmarks, one for user bookmarks, one for the personal server bookmarks (server documents only), one for other users' shared bookmarks (server documents only) and one for temporary bookmarks (server documents only).

At the top of the dialog a list of all bookmarks currently defined for the QlikView document are found. The bookmarks are described and may be sorted by several columns:

Bookmarks dialog columns

Column	Description
Show	Enable this option if the bookmark should appear in bookmark object listings and in the Bookmarks menu. If the check box is left unchecked, the bookmark will not appear in those places, but will remain accessible via this dialog.
Name	Name of the bookmarks. To sort the bookmarks in alphabetical order, click the header of the column. If clicked twice, the bookmarks are sorted in reverse alphabetical order.
+	If the check box is marked for a bookmark, that bookmark will be applied without first clearing existing selections in the document. A bookmark can only be applied on top of existing selections if they do not conflict with the selections in the document.
Layout	If the bookmark was created complete with layout information, use the checkbox to toggle the layout setting for the bookmark. When the layout setting is on, the program will attempt to recreate the layout that prevailed when the bookmark was created. This includes switching to the correct sheet and updating the layout of any sheet objects on that sheet. This setting cannot be used to add layout information to a bookmark that was originally created without it.
Created	Timestamp information on when bookmarks were created.

Column	Description
ID	<p>This is used for macro purposes. Every sheet object is assigned a unique ID. We recommend that you use alphanumeric characters only in the ID. For bookmarks, the ID starts with BM01. Linked objects share the same object ID. You may edit this ID number later on. This means it is possible to have a document bookmark and a server bookmark with the same ID.</p> <p>A bookmark ID may be changed via a macro to any other string that is currently not used as ID for any other bookmark, sheet or sheet object in the document. Renaming the bookmark does not change the bookmark ID. Exporting and then importing a bookmark will create a new bookmark ID. The bookmark ID may be preceded by a prefix describing its type (document, user etc.).</p>
Popup	If info text has been added to the bookmark, checking this alternative shows it as a popup text.
Info Text	If info text has been added to the bookmark, it is displayed here.
Share	<p>This check box is only available in the My Server Bookmarks page. By marking it for one of the personal server bookmarks, it makes that bookmark available to other authenticated users of the same server document in their Shared Server Bookmarks page. The bookmark will stay in the My Server Bookmarks page and will not appear in the Shared Server Bookmarks page.</p> <p>It is possible to revoke the sharing at any time by deselecting the check box.</p>

At the bottom of the dialog , you find a number of buttons that can be used to perform actions with the bookmark currently selected in the list above.

Bookmarks dialog buttons

Button	Action
Select	Displays the selected bookmark on the screen.
Replace	Replaces the selected bookmark with the current selections. Only bookmarks that you have created can be replaced.
Rename	Opens the Rename Bookmark dialog where it is possible to specify a new name for the bookmark. Only bookmarks that you have created can be renamed.
Remove	Removes the selected bookmark. Only bookmarks that you have created can be removed.
Clear All	Removes all bookmarks in the current pane of the dialog. Only bookmarks that you have created can be removed.
Set Clear State	Click this button if you want to use the selection of the highlighted bookmark as clear state.
Edit Info	Here it is possible to edit the info text.

Button	Action
Import	After browsing for and selecting a previously saved bookmark (.qbm) file, the Import Bookmarks dialog will open to import bookmarks.
Export	Opens the Export Bookmarks dialog where it is possible to export selected bookmarks to a QlikView bookmark (.qbm) file.
Promote	Moves the selected bookmark one step up in the list. It is also possible to do this by clicking and dragging it to any position in the list. <div style="border: 1px solid #ccc; padding: 5px; margin-top: 10px;">  <i>This is not available in server documents.</i> </div>
Demote	Moves the selected bookmark one step down in the list. <div style="border: 1px solid #ccc; padding: 5px; margin-top: 10px;">  <i>This is not available in server documents.</i> </div>
Move Local User Bookmarks to Server	This text only appears when working with a server document and in the User Bookmarks tab. By clicking on the text it is possible to convert all the local user bookmarks to server bookmarks, stored in the server repository. This is a recommended practice as the personal server bookmarks will stay accessible via the server even if changing computer or if the server document is renamed. Before the conversion takes place, the system asks for confirmation. The conversion is all-or-nothing (within the active document) and one-way only.

Export Bookmark(s)

In the **Export Bookmarks** dialog a list of all bookmarks that have been defined in the current document, is found. Only those bookmarks that are ticked will be included in the exported bookmark (.qbm) file.

On clicking **OK** the specification of a file name and location for the bookmark file will be requested.. Once saved, the bookmark file can be kept for later use or distributed to other users of the same QlikView document.

Import Bookmarks

Bookmarks are imported to a bookmark file by choosing **Import...** from the **Bookmarks** menu. It opens a browse dialog where a QlikView bookmark file (.qbm extension) can be selected. The **Import Bookmark** dialog will then open.

In the **Import Bookmarks** dialog, a list of all bookmarks that are included in the selected bookmark file, are found.

Bookmarks should only be imported to a QlikView document containing fields and field values to which the bookmarks refer.

- **Bookmarks Available for Import:** To the left all the bookmarks which were defined in the bookmark file are listed.
- **Current Bookmarks:** To the right a list of existing user bookmarks or document bookmarks in the document is shown. Bookmarks must be imported either as a user bookmark or as a document bookmark. The radio buttons at the top of the dialog governs how the bookmark is imported.
- **Import:** Highlight one or more bookmarks in the **Bookmarks Available for Import** list and press this button to import them.
- **Rename:** Opens the **Rename Bookmark** dialog where a new name for the highlighted bookmark can be specified before import.

Alternate States and Bookmarks

Bookmarks capture selections in all states defined in the QlikView document. When recalling a bookmark, the selections in all states will be applied.

It is possible to make use of specific states contained in a bookmark within an expression. For example, this expression calculates Sales over the set generated by the selections defined in bookmark BM01 for the state 'Group 1'.

Example:

```
sum({[Group 1]:BM01} Sales)
```

Bookmarks that reference a state that no longer exists (the state was removed by a developer) will ignore the missing state(s).

9 Script syntax and chart functions

In the script, the name of the data source, the names of the tables and the names of the fields included in the logic are defined. Furthermore, the fields in the access rights definition are defined in the script.

The script consists of a number of statements that are executed consecutively.

The QlikView command line syntax and script syntax are described in a notation called Backus-Naur Formalism, or BNF code.

The first lines of code are already generated when a new QlikView file is created. The default values of these number interpretation variables are derived from the regional settings of the OS.

In the script the name of the data source, the names of the tables and the names of the fields included in the logic are defined. The script consists of a number of script statements and keywords that are executed consecutively.

For a table file with commas, tabs or semicolons as delimiter, the **LOAD**-statement may be used. By default the **LOAD**-statement will load all fields of the file.

A general database must be accessed through Microsoft ODBC. Here standard SQL statements are used. The SQL syntax accepted differs between different ODBC drivers.

All script statements must end with a semicolon, ";".

A detailed description of script syntax can be accessed via the topics in this section.

9.1 What is Backus-Naur formalism?

The QlikView command line syntax and script syntax are described in a notation called Backus-Naur formalism, also known as BNF code.

The following table provides a list of symbols used in BNF code, with a description of how they are interpreted:

BNF code symbols

Symbol	Description
	Logical OR: the symbol on either side can be used.
()	Parentheses defining precedence: used for structuring the BNF syntax.
[]	Square brackets: enclosed items are optional.
{ }	Braces: enclosed items may be repeated zero or more times.
Symbol	A non-terminal syntactic category, that: can be divided further into other symbols. For example, compounds of the above, other non-terminal symbols, text strings, and so on.
::=	Marks the beginning of a block that defines a symbol.
LOAD	A terminal symbol consisting of a text string. Should be written as it is into the script.

All terminal symbols are printed in a **bold face** font. For example, "(" should be interpreted as a parenthesis defining precedence, whereas "(" should be interpreted as a character to be printed in the script.

Example:

The description of the alias statement is:

```
alias fieldname as aliasname { , fieldname as aliasname }
```

This should be interpreted as the text string "alias", followed by an arbitrary field name, followed by the text string "as", followed by an arbitrary alias name. Any number of additional combinations of "fieldname as alias" may be given, separated by commas.

The following statements are correct:

```
alias a as first;  
alias a as first, b as second;  
alias a as first, b as second, c as third;
```

The following statements are not correct:

```
alias a as first b as second;  
alias a as first { , b as second };
```

9.2 Functions

A function is a type of procedure or routine that performs a specific task on data in documents. QlikView provides several hundred functions that can be used for various purposes, such as: to perform calculations, interpret data or system information, determine conditions, and so on.

Many functions can be used both in the script editor and in charts. Some functions are specific to charts (chart functions), and others are specific to the script editor (script functions).

Functions are often, but not always, used in expressions.

The following list shows some examples of functions:

- **Max**: an aggregation function that can be used in scripts and charts.
For example: **Max(Sales)** calculates the highest value in the field Sales.
- **IF**: a conditional function that can be used in scripts and charts.
For example: **IF(Amount>0, 'OK', 'Alarm')** determines if the condition 'is the value of Amount greater than zero?' is met. If it is, OK is written, otherwise Alarm is written.
- **Date#**: an interpretation function that can be used in scripts and charts.
For example **Date#(A)** takes the input value **A** and evaluates it as a date.

9.3 Script statements and keywords

The QlikView script consists of a number of statements. A statement can be either a regular script statement or a script control statement. Certain statements can be preceded by prefixes.

Regular statements are typically used for manipulating data in one way or another. These statements may be written over any number of lines in the script and must always be terminated by a semicolon, ";".

Control statements are typically used for controlling the flow of the script execution. Each clause of a control statement must be kept inside one script line and may be terminated by a semicolon or the end-of-line.

Prefixes may be applied to applicable regular statements but never to control statements. The **when** and **unless** prefixes can, however, be used as suffixes to a few specific control statement clauses.

In the next subchapter, an alphabetical listing of all script statements, control statements and prefixes, are found.

All script keywords can be typed with any combination of lower case and upper case characters. Field and variable names used in the statements are however case sensitive.

Script control statements

The QlikView script consists of a number of statements. A statement can be either a regular script statement or a script control statement.

Control statements are typically used for controlling the flow of the script execution. Each clause of a control statement must be kept inside one script line and may be terminated by semicolon or end-of-line.

Prefixes are never applied to control statements, with the exceptions of the prefixes **when** and **unless** which may be used with a few specific control statements.

All script keywords can be typed with any combination of lower case and upper case characters.

Script control statements overview

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

Call

The **call** control statement calls a subroutine which must be defined by a previous **sub** statement.

```
Call name ( [ paramlist ] )
```

Do..loop

The **do..loop** control statement is a script iteration construct which executes one or several statements until or while a logical condition is met.

```
Do..loop [ ( while | until ) condition ] [statements]  
[exit do [ ( when | unless ) condition ] [statements]  
loop [ ( while | until ) condition ]
```

Exit script

This control statement stops script execution. It may be inserted anywhere in the script.

```
Exit script [ (when | unless) condition ]
```

For each ..next

The **for each..next** control statement is a script iteration construct which executes one or several statements for each value in a comma separated list. The statements inside the loop enclosed by **for** and **next** will be executed for each value of the list.

```
For each..next var in list  
[statements]  
[exit for [ ( when | unless ) condition ]  
[statements]  
next [var]
```

For..next

The **for..next** control statement is a script iteration construct with a counter. The statements inside the loop enclosed by **for** and **next** will be executed for each value of the counter variable between (and including) specified low and high limits.

```
For..next counter = expr1 to expr2 [ stepexpr3 ]  
[statements]  
[exit for [ ( when | unless ) condition ]  
[statements]  
Next [counter]
```

If..then

The **if..then** control statement is a script selection construct forcing the script execution to follow different paths depending on one or several logical conditions.

*Since the **if..then** statement is a control statement and as such is ended with either a semicolon or end-of-line, each of its four possible clauses (**if..then**, **elseif..then**, **else** and **end if**) must not cross a line boundary.*

```
If..then..elseif..else..end if condition then  
[ statements ]  
{ elseif condition then  
[ statements ] }  
[ else  
[ statements ] ]  
end if
```

Sub

The **sub..end sub** control statement defines a subroutine which can be called upon from a **call** statement.

```
Sub..end sub name [ ( paramlist ) ] statements end sub
```

Switch

The **switch** control statement is a script selection construct forcing the script execution to follow different paths, depending on the value of an expression.

```
Switch..case..default..end switch expression {case valuelist [ statements ]}  
[default statements] end switch
```

Call

The **call** control statement calls a subroutine which must be defined by a previous **sub** statement.

Syntax:

```
Call name ( [ paramlist ])
```

Arguments:

Call arguments

Argument	Description
name	The name of the subroutine.
paramlist	A comma separated list of the actual parameters to be sent to the subroutine. Each item in the list may be a field name, a variable or an arbitrary expression.

The subroutine called by a **call** statement must be defined by a **sub** encountered earlier during script execution.

Parameters are copied into the subroutine and, if the parameter in the **call** statement is a variable and not an expression, copied back out again upon exiting the subroutine.

Limitations:

Since the **call** statement is a control statement and as such is ended with either a semicolon or end-of-line, it must not cross a line boundary.

Example 1:

```
// Example 1
Sub INCR (I,J)
    I = I + 1
    Exit Sub when I < 10
    J = J + 1
End Sub
Call INCR (X,Y)
```

Example 2:

```
// Example 2 - List all QV related files on disk
sub DoDir (Root)
    For Each Ext in 'qvw', 'qvo', 'qvs', 'qvt', 'qvd', 'qvc'
        For Each File in fileList (Root&'\'*.' &Ext)
            LOAD
```

```

'$(File)' as Name, FileSize( '$(File)' ) as
Size, FileTime( '$(File)' ) as FileTime
autogenerate 1;

    Next File

Next Ext
For Each Dir in dirlist (Root&'\'*\' )

    Call DoDir (Dir)

Next Dir

End Sub
Call DoDir ('c:')

```

Do..loop

The **do..loop** control statement is a script iteration construct which executes one or several statements until or while a logical condition is met.

Syntax:

```

Do [ ( while | until ) condition ] [statements]
[exit do [ ( when | unless ) condition ] [statements]
loop[ ( while | until ) condition ]

```

Since the **do..loop** statement is a control statement and as such is ended with either a semicolon or end-of-line, each of its three possible clauses (**do**, **exit do** and **loop**) must not cross a line boundary.

Arguments:

Do arguments

Argument	Description
condition	A logical expression evaluating to True or False.
statements	Any group of one or more QlikView script statements.
while / until	The while or until conditional clause must only appear once in any do..loop statement, i.e. either after do or after loop . Each condition is interpreted only the first time it is encountered but is evaluated for every time it encountered in the loop.
exit do	If an exit do clause is encountered inside the loop, the execution of the script will be transferred to the first statement after the loop clause denoting the end of the loop. An exit do clause can be made conditional by the optional use of a when or unless suffix.

Example:

```

// LOAD files file1.csv..file9.csv
Set a=1;
Do while a<10
LOAD * from file$(a).csv;

```

```
Let a=a+1;
Loop
```

Exit script

This control statement stops script execution. It may be inserted anywhere in the script.

Syntax:

```
Exit Script [ ( when | unless ) condition ]
```

Since the **exit script** statement is a control statement and as such is ended with either a semicolon or end-of-line, it must not cross a line boundary.

Arguments:

Exit script arguments

Argument	Description
condition	A logical expression evaluating to True or False.
when / unless	An exit script statement can be made conditional by the optional use of when or unless clause.

Examples:

```
//Exit script
Exit Script;

//Exit script when a condition is fulfilled
Exit Script when a=1
```

For..next

The **for..next** control statement is a script iteration construct with a counter. The statements inside the loop enclosed by **for** and **next** will be executed for each value of the counter variable between (and including) specified low and high limits.

Syntax:

```
For counter = expr1 to expr2 [ step expr3 ]
[statements]
[exit for [ ( when | unless ) condition ]
[statements]
Next [counter]
```

The expressions *expr1*, *expr2* and *expr3* are only evaluated the first time the loop is entered. The value of the counter variable may be changed by statements inside the loop, but this is not good programming practice.

If an **exit for** clause is encountered inside the loop, the execution of the script will be transferred to the first statement after the **next** clause denoting the end of the loop. An **exit for** clause can be made conditional by the optional use of a **when** or **unless** suffix.

Since the **for..next** statement is a control statement and as such is ended with either a semicolon or end-of-line, each of its three possible clauses (**for..to..step**, **exit for** and **next**) must not cross a line boundary.

Arguments:

For arguments

Argument	Description
counter	A variable name. If <i>counter</i> is specified after next it must be the same variable name as the one found after the corresponding for .
expr1	An expression which determines the first value of the <i>counter</i> variable for which the loop should be executed.
expr2	An expression which determines the maximum value of the <i>counter</i> variable for which the loop should be executed.
expr3	An expression which determines the value indicating the increment of the <i>counter</i> variable each time the loop has been executed.
condition	a logical expression evaluating to True or False.
statements	Any group of one or more QlikView script statements.

Example 1: Loading a sequence of files

```
// LOAD files file1.csv..file9.csv
for a=1 to 9
    LOAD * from file$(a).csv;
next
```

Example 2: Loading a random number of files

In this example, we assume there are data files *x1.csv*, *x3.csv*, *x5.csv*, *x7.csv* and *x9.csv*. Loading is stopped at a random point using the `if rand()<0.5 then` condition.

```
for counter=1 to 9 step 2
    set filename=x$(counter).csv;
    if rand( )<0.5 then
        exit for unless counter=1
    end if
    LOAD a,b from $(filename);
next
```

For each..next

The **for each..next** control statement is a script iteration construct which executes one or several statements for each value in a comma separated list. The statements inside the loop enclosed by **for** and **next** will be executed for each value of the list.

Syntax:

Special syntax makes it possible to generate lists with file and directory names in the current directory.

```
for each var in list
[statements]
[exit for [ ( when | unless ) condition ]
[statements]
next [var]
```

Arguments:

For each arguments

Argument	Description
var	A script variable name which will acquire a new value from list for each loop execution. If var is specified after next it must be the same variable name as the one found after the corresponding for each .

The value of the **var** variable may be changed by statements inside the loop, but this is not good programming practice.

If an **exit for** clause is encountered inside the loop, the execution of the script will be transferred to the first statement after the **next** clause denoting the end of the loop. An **exit for** clause can be made conditional by the optional use of a **when** or **unless** suffix.

*Since the **for each..next** statement is a control statement and as such is ended with either a semicolon or end-of-line, each of its three possible clauses (**for each**, **exit for** and **next**) must not cross a line boundary.*

Syntax:

```
list := item { , item }
item := constant | (expression) | filelist (mask) | dirlist (mask) |
fieldvaluelist (fieldname)
```

List arguments

Argument	Description
constant	Any number or string. Note that a string written directly in the script must be enclosed by single quotes. A string without single quotes will be interpreted as a variable, and the value of the variable will be used. Numbers do not need to be enclosed by single quotes.
expression	An arbitrary expression.
mask	A filename or folder name mask which may include any valid filename characters as well as the standard wildcard characters, * and ?.
condition	A logical expression evaluating to True or False.
statements	Any group of one or more QlikView script statements.
filelist mask	This syntax produces a comma separated list of all files in the current directory matching the filename mask.
dirlist mask	This syntax produces a comma separated list of all folders in the current folder matching the folder name mask.
fieldvaluelist mask	This syntax iterates through the values of a field already loaded into QlikView.

The Qlik Web Storage Provider Connectors and other DataFiles connections do not support filter masks that use wildcard (and ?) characters.*

Example 1: Loading a list of files

```
// LOAD the files 1.csv, 3.csv, 7.csv and xyz.csv
for each a in 1,3,7,'xyz'
    LOAD * from file$(a).csv;
next
```

Example 2: Creating a list of files on disk

This example loads a list of all QlikView related files in a folder.

```
sub DoDir (Root)
    for each Ext in 'qvw', 'qva', 'qvo', 'qvs', 'qvc', 'qvd'

        for each File in filelist (Root&'*. ' &Ext)

            LOAD
                '$(File)' as Name,
                FileSize( '$(File)' ) as Size,
                FileTime( '$(File)' ) as FileTime
            autogenerate 1;

        next File
    end for
end sub
```

```
next Ext
for each Dir in dirlist (Root&'\'*\' )

    call DoDir (Dir)

next Dir

end sub

call DoDir ('C:')
```

Example 3: Iterating through a the values of a field

This example iterates through the list of loaded values of FIELD and generates a new field, NEWFIELD. For each value of FIELD, two NEWFIELD records will be created.

```
Load * inline [
FIELD
one
two
three
];

FOR Each a in FieldValueList('FIELD')
LOAD '$(a)' &'-'&RecNo() as NEWFIELD AutoGenerate 2;
NEXT a
```

The resulting table looks like this:

Example 3

NEWFIELD
one-1
one-2
two-1
two-2
three-1
three-2

If..then..elseif..else..end if

The **if..then** control statement is a script selection construct forcing the script execution to follow different paths depending on one or several logical conditions.

Control statements are typically used to control the flow of the script execution. In a chart expression, use the **if** conditional function instead.

Syntax:

```
If condition then
[ statements ]
{ elseif condition then
```

```
[ statements ] }  
[ else  
  [ statements ] ]  
end if
```

Since the **if..then** statement is a control statement and as such is ended with either a semicolon or end-of-line, each of its four possible clauses (**if..then**, **elseif..then**, **else** and **end if**) must not cross a line boundary.

Arguments:

If arguments

Argument	Description
condition	A logical expression which can be evaluated as True or False.
statements	Any group of one or more QlikView script statements.

Example 1:

```
if a=1 then  
    LOAD * from abc.csv;  
    SQL SELECT e, f, g from tab1;  
end if
```

Example 2:

```
if a=1 then; drop table xyz; end if;
```

Example 3:

```
if x>0 then  
    LOAD * from pos.csv;  
elseif x<0 then  
    LOAD * from neg.csv;  
else  
    LOAD * from zero.txt;  
end if
```

Sub..end sub

The **sub..end sub** control statement defines a subroutine which can be called upon from a **call** statement.

Syntax:

```
Sub name [ ( paramlist ) ] statements end sub
```

9 Script syntax and chart functions

Arguments are copied into the subroutine and, if the corresponding actual parameter in the **call** statement is a variable name, copied back out again upon exiting the subroutine.

If a subroutine has more formal parameters than actual parameters passed by a **call** statement, the extra parameters will be initialized to NULL and can be used as local variables within the subroutine.

Since the **sub** statement is a control statement and as such is ended with either a semicolon or end-of-line, each of its two clauses (**sub** and **end sub**) must not cross a line boundary.

Arguments:

Sub arguments

Argument	Description
name	The name of the subroutine.
paramlist	A comma separated list of variable names for the formal parameters of the subroutine. These can be used as any variable inside the subroutine.
statements	Any group of one or more QlikView script statements.

Example 1:

```
Sub INCR (I,J)
I = I + 1
Exit Sub when I < 10
J = J + 1
End Sub
Call INCR (X,Y)
```

Example 2: - parameter transfer

```
Sub ParTrans (A,B,C)
A=A+1
B=B+1
C=C+1
End Sub
A=1
X=1
C=1
Call ParTrans (A, (X+1)*2)
```

The result of the above will be that locally, inside the subroutine, A will be initialized to 1, B will be initialized to 4 and C will be initialized to NULL.

When exiting the subroutine, the global variable A will get 2 as value (copied back from subroutine). The second actual parameter “(X+1)*2” will not be copied back since it is not a variable. Finally, the global variable C will not be affected by the subroutine call.

Switch..case..default..end switch

The **switch** control statement is a script selection construct forcing the script execution to follow different paths, depending on the value of an expression.

Syntax:

```
Switch expression {case valuelist [ statements ]} [default statements] end  
switch
```

Since the **switch** statement is a control statement and as such is ended with either a semicolon or end-of-line, each of its four possible clauses (**switch**, **case**, **default** and **end switch**) must not cross a line boundary.

Arguments:

Switch arguments

Argument	Description
expression	An arbitrary expression.
valuelist	A comma separated list of values with which the value of expression will be compared. Execution of the script will continue with the statements in the first group encountered with a value in valuelist equal to the value in expression. Each value in valuelist may be an arbitrary expression. If no match is found in any case clause, the statements under the default clause, if specified, will be executed.
statements	Any group of one or more QlikView script statements.

Example:

```
Switch I  
Case 1  
LOAD '$(I): CASE 1' as case autogenerate 1;  
Case 2  
LOAD '$(I): CASE 2' as case autogenerate 1;  
Default  
LOAD '$(I): DEFAULT' as case autogenerate 1;  
End Switch
```

Script prefixes

Prefixes may be applied to applicable regular statements but never to control statements. The **when** and **unless** prefixes can, however, be used as suffixes to a few specific control statement clauses.

All script keywords can be typed with any combination of lower case and upper case characters. Field and variable names used in the statements are however case sensitive.

Script prefixes overview

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

Add

The **add** prefix can be added to any **LOAD**, **SELECT** or **map...using** statement in the script. It is only relevant during partial reloads.

```
Add [only] (loadstatement | selectstatement | mapstatement)
```

Buffer

QVD files can be created and maintained automatically via the **buffer** prefix. This prefix can be used on most **LOAD** and **SELECT** statements in script. It indicates that QVD files are used to cache/buffer the result of the statement.

```
Buffer[(option [ , option])] ( loadstatement | selectstatement )  
option::= incremental | stale [after] amount [(days | hours)]
```

Bundle

The **Bundle** prefix is used to include external files, such as image or sound files, or objects connected to a field value, to be stored in the QlikView file.

```
Bundle [Info] ( loadstatement | selectstatement)
```

Concatenate

If two tables that are to be concatenated have different sets of fields, concatenation of two tables can still be forced with the **Concatenate** prefix.

```
Concatenate [ (tablename ) ] ( loadstatement | selectstatement )
```

Crosstable

The **crosstable** prefix is used to turn a cross table into a straight table, that is, a wide table with many columns is turned into a tall table, with the column headings being placed into a single attribute column.

```
Crosstable (attribute field name, data field name [ , n ] ) ( loadstatement |  
selectstatement )
```

First

The **First** prefix to a **LOAD** or **SELECT (SQL)** statement is used for loading a set maximum number of records from a data source table.

```
First n( loadstatement | selectstatement )
```

Generic

The **generic** prefix unpacks a tall table, creating one field per attribute value. This is similar to pivoting a table, except that it results in a separate table per field created.

```
Generic ( loadstatement | selectstatement )
```

Hierarchy

The **hierarchy** prefix is used to transform a parent-child hierarchy table to a table that is useful in a QlikView data model. It can be put in front of a **LOAD** or a **SELECT** statement and will use the result of the loading statement as input for a table transformation.

```
Hierarchy (NodeID, ParentID, NodeName, [ParentName], [PathSource],  
[PathName], [PathDelimiter], [Depth]) (loadstatement | selectstatement)
```

HierarchyBelongsTo

This prefix is used to transform a parent-child hierarchy table to a table that is useful in a QlikView data model. It can be put in front of a **LOAD** or a **SELECT** statement and will use the result of the loading statement as input for a table transformation.

```
HierarchyBelongsTo (NodeID, ParentID, NodeName, AncestorID, AncestorName,  
[DepthDiff]) (loadstatement | selectstatement)
```

Image_Size

This clause is used with the **Info** prefix or the **Bundle** prefix to resize images from a database management system to fit in the fields.

```
Info [Image_Size(width,height )] ( loadstatement | selectstatement )
```

Info

The **info** prefix is used to link external information, such as a text file, a picture or a video to a field value.

```
Info( loadstatement | selectstatement )
```

Inner

The **join** and **keep** prefixes can be preceded by the prefix **inner**. If used before **join** it specifies that an inner join should be used. The resulting table will thus only contain combinations of field values from the raw data tables where the linking field values are represented in both tables. If used before **keep**, it specifies that both raw data tables should be reduced to their common intersection before being stored in QlikView. .

```
Inner ( Join | Keep) [ (tablename) ](loadstatement |selectstatement )
```

Inputfield

A field may be flagged as an input field by listing it in an **inputfield** statement before it is referenced in any **load** or **select** statements.

```
Inputfield (page 915) fieldlist
```

IntervalMatch

The **IntervalMatch** prefix is used to create a table matching discrete numeric values to one or more numeric intervals, and optionally matching the values of one or several additional keys.

```
IntervalMatch (matchfield)(loadstatement | selectstatement )  
IntervalMatch (matchfield,keyfield1 [ , keyfield2, ... keyfield5 ] )  
(loadstatement | selectstatement )
```

Join

The **join** prefix joins the loaded table with an existing named table or the last previously created data table.

```
[Inner | Outer | Left | Right ] Join [ (tablename) ]( loadstatement |  
selectstatement )
```

Keep

The **keep** prefix is similar to the **join** prefix. Just as the **join** prefix, it compares the loaded table with an existing named table or the last previously created data table, but instead of joining the loaded table with an existing table, it has the effect of reducing one or both of the two tables before they are stored in QlikView, based on the intersection of table data. The comparison made is equivalent to a natural join made over all the common fields, i.e. the same way as in a corresponding join. However, the two tables are not joined and will be kept in QlikView as two separately named tables.

```
(Inner | Left | Right) Keep [ (tablename) ] ( loadstatement | selectstatement )
```

Left

The **Join** and **Keep** prefixes can be preceded by the prefix **left**.

If used before **join** it specifies that a left join should be used. The resulting table will only contain combinations of field values from the raw data tables where the linking field values are represented in the first table. If used before **keep**, it specifies that the second raw data table should be reduced to its common intersection with the first table, before being stored in QlikView.

```
Left ( Join | Keep ) [ (tablename) ] ( loadstatement | selectstatement )
```

Mapping

The **mapping** prefix is used to create a mapping table that can be used to, for example, replacing field values and field names during script execution.

```
Mapping ( loadstatement | selectstatement )
```

NoConcatenate

The **NoConcatenate** prefix forces two loaded tables with identical field sets to be treated as two separate internal tables, when they would otherwise be automatically concatenated.

```
NoConcatenate ( loadstatement | selectstatement )
```

Outer

The explicit **Join** prefix can be preceded by the prefix **outer** in order to specify an outer join. In an outer join all combinations between the two tables are generated. The resulting table will thus contain combinations of field values from the raw data tables where the linking field values are represented in one or both tables. The **outer** keyword is optional.

```
Outer Join [ (tablename) ] ( loadstatement | selectstatement )
```

Replace

The **replace** prefix is used to drop the entire QlikView table and replace it with a new table that is loaded or selected.

```
Replace[only] ( loadstatement | selectstatement | map...usingstatement )
```

Right

The **Join** and **Keep** prefixes can be preceded by the prefix **right**.

9 Script syntax and chart functions

If used before **join** it specifies that a right join should be used. The resulting table will only contain combinations of field values from the raw data tables where the linking field values are represented in the second table. If used before **keep**, it specifies that the first raw data table should be reduced to its common intersection with the second table, before being stored in QlikView.

```
Right (Join | Keep) [(tablename)] (loadstatement | selectstatement )
```

Sample

The **sample** prefix to a **LOAD** or **SELECT** statement is used for loading a random sample of records from the data source.

```
Sample p ( loadstatement | selectstatement )
```

Semantic

Tables containing relations between records can be loaded through a **semantic** prefix. This can for example be self-references within a table, where one record points to another, such as parent, belongs to, or predecessor.

```
Semantic ( loadstatement | selectstatement)
```

Unless

The **unless** prefix and suffix is used for creating a conditional clause which determines whether a statement or exit clause should be evaluated or not. It may be seen as a compact alternative to the full **if..end if** statement.

```
(Unless condition statement | exitstatement Unless condition )
```

When

The **when** prefix and suffix is used for creating a conditional clause which determines whether a statement or exit clause should be executed or not. It may be seen as a compact alternative to the full **if..end if** statement.

```
( When condition statement | exitstatement when condition )
```

Add

The **Add** prefix can be added to any **LOAD** or **SELECT** statement in the script to specify that it should add records to another table. It also specifies that this statement should be run in a partial reload. The **Add** prefix can also be used in a **Map** statement.

Syntax:

```
Add[only] [Concatenate [(tablename)]] (loadstatement | selectstatement)
```

```
Add[only] mapstatement
```

During a normal (non-partial) reload, the **AddLOAD** construction will work as a normal **LOAD** statement. Records will be generated and stored in a table.

9 Script syntax and chart functions

If the **Concatenate** prefix is used, or if there exists a table with the same set of fields, the records will be appended to the relevant existing table. Otherwise, the **AddLOAD** construction will create a new table.

A partial reload will do the same. The only difference is that the **AddLOAD** construction will never create a new table. There always exists a relevant table from the previous script execution to which the records should be appended.

No check for duplicates is performed. Therefore, a statement using the **Add** prefix will often include either a distinct qualifier or a where clause guarding duplicates.

The **Add Map...Using** statement causes mapping to take place also during partial script execution.

Arguments:

Add arguments

Argument	Description
only	An optional qualifier denoting that the statement should be disregarded during normal (non-partial) reloads.

Examples and results:

Examples and results

Example	Result
Tab1: LOAD Name, Number FROM Persons.csv; Add LOAD Name, Number FROM newPersons.csv;	<p>During normal reload, data is loaded from <i>Persons.csv</i> and stored in the QlikView table Tab1. Data from <i>NewPersons.csv</i> is then concatenated to the same QlikView table.</p> <p>During partial reload, data is loaded from <i>NewPersons.csv</i> and appended to the QlikView table Tab1. No check for duplicates is made.</p>
Tab1: SQL SELECT Name, Number FROM Persons.csv; Add LOAD Name, Number FROM NewPersons.csv (txt) where not exists(Name);	<p>A check for duplicates is made by means of looking if Name exists in the previously loaded table data (see the function exists under inter-record functions).</p> <p>During normal reload, data is loaded from <i>Persons.csv</i> and stored in the QlikView table Tab1. Data from <i>NewPersons.csv</i> is then concatenated to the same QlikView table.</p> <p>During partial reload, data is loaded from <i>NewPersons.csv</i> which is appended to the QlikView table Tab1. A check for duplicates is made by means of seeing if Name exists in the previously loaded table data.</p>
Tab1: LOAD Name, Number FROM Persons.csv; Add Only LOAD Name, Number FROM NewPersons.csv (txt) where not exists(Name);	<p>During normal reload, data is loaded from <i>Persons.csv</i> and stored in the QlikView table Tab1. The statement loading <i>NewPersons.csv</i> is disregarded.</p> <p>During partial reload, data is loaded from <i>NewPersons.csv</i> which is appended to the QlikView table Tab1. A check for duplicates is made by means of seeing if Name exists in the previously loaded table data.</p>

Buffer

QVD files can be created and maintained automatically via the **buffer** prefix. This prefix can be used on most **LOAD** and **SELECT** statements in script. It indicates that QVD files are used to cache/buffer the result of the statement.

Syntax:

```
Buffer [(option [ , option])] ( loadstatement | selectstatement )  
option::= incremental | stale [after] amount [(days | hours)]
```

If no option is used, the QVD buffer created by the first execution of the script will be used indefinitely.

QVD buffers are stored in *C:\ProgramData\QlikTech\QlikView\Buffers* by default.

QVD buffers will normally be removed when no longer referenced anywhere throughout a complete script execution in the document that created it or when the document that created it no longer exists.

Arguments:

Buffer arguments

Argument	Description
incremental	The incremental option enables the ability to read only part of an underlying file. Previous size of the file is stored in the XML header in the QVD file. This is particularly useful with log files. All records loaded at a previous occasion are read from the QVD file whereas the following new records are read from the original source and finally an updated QVD-file is created. Note that the incremental option can only be used with LOAD statements and text files and that incremental load cannot be used where old data is changed or deleted!
stale [after] amount [(days hours)]	amount is a number specifying the time period. Decimals may be used. The unit is assumed to be days if omitted. The stale after option is typically used with DB sources where there is no simple timestamp on the original data. Instead you specify how old the QVD snapshot can be to be used. A stale after clause simply states a time period from the creation time of the QVD buffer after which it will no longer be considered valid. Before that time the QVD buffer will be used as source for data and after that the original data source will be used. The QVD buffer file will then automatically be updated and a new period starts.

Limitations:

Numerous limitations exist, most notable is that there must be either a file **LOAD** or a **SELECT** statement at the core of any complex statement.

Example 1:

```
Buffer SELECT * from MyTable;
```

Example 2:

```
Buffer (stale after 7 days) SELECT * from MyTable;
```

Example 3:

```
Buffer (incremental) LOAD * from MyLog.log;
```

Bundle

The **Bundle** prefix is used to include external files, such as image or sound files, or objects connected to a field value, to be stored in the QlikView file.

Syntax:

```
Bundle [Info] ( loadstatement | selectstatement)
```

In order to maintain portability, it is possible to include the external files into the QlikView file itself. To this end use the **Bundle** prefix. The bundled info files are compressed in the process, but will nevertheless take up additional space both in the file and in RAM. Therefore consider both the size and the number of bundled files before going for this solution.

The info may be referenced from the layout as normal info, via the chart info function or as an internal file via the special syntax **qmem:// fieldname / fieldvalue** alternatively **qmem:// fieldname / < index >** where index is the internal index of a field value.

Arguments:

Bundle arguments

Argument	Description
loadstatement selectstatement	If a piece of external information, such as an image or a sound file is to be connected to a field value, this is done in a table that is loaded with the Info prefix. The Info prefix may be omitted when Bundle is used.

Example:

```
Bundle Info LOAD * From flagoecd.csv;  
Bundle SQL SELECT * from infotable;
```

Concatenate

If two tables that are to be concatenated have different sets of fields, concatenation of two tables can still be forced with the **Concatenate** prefix. This statement forces concatenation with an existing named table or the latest previously created logical table. An automatic concatenation occurs if two tables have the same field names.

Syntax:

```
Concatenate [ (tablename ) ] ( loadstatement | selectstatement )
```

A concatenation is in principle the same as the **SQL UNION** statement, but with two differences:

- The **Concatenate** prefix can be used no matter if the tables have identical field names or not.
- Identical records are not removed with the **Concatenate** prefix.

Arguments:

Concatenate arguments

Argument	Description
tablename	The name of the existing table.

Example 1:

```
LOAD * From file2.csv;  
Concatenate SELECT * From table3;
```

Example 2:

```
tab1:  
LOAD * From file1.csv;  
tab2:  
LOAD * From file2.csv;  
.. ..  
Concatenate (tab1) LOAD * From file3.csv;
```

Crosstable

The **crosstable** prefix is used to turn a cross table into a straight table, that is, a wide table with many columns is turned into a tall table, with the column headings being placed into a single attribute column.

Syntax:

```
crosstable (attribute field name, data field name [ , n ] ) ( loadstatement |  
selectstatement )
```

Arguments:

Crosstable arguments

Argument	Description
attribute field name	The field that contains the attribute values.
data field name	The field that contains the data values.
n	The number of qualifier fields preceding the table to be transformed to generic form. Default is 1.

9 Script syntax and chart functions

A crosstable is a common type of table featuring a matrix of values between two or more orthogonal lists of header data, of which one is used as column headers. A typical example could be to have one column per month. The result of the **crosstable** prefix is that the column headers (for example month names) will be stored in one field, the attribute field, and the column data (month numbers) will be stored in a second field: the data field.

Example:

```
Crosstable (Month, Sales, 2) LOAD * INLINE[
Person, Location, Jan, Feb, Mar
Bob, London, 100, 200, 300
Kate, New York, 400, 500, 600
];
```

Result:

Example 1

Person,	Location,	Month,	Sales
Bob,	London,	Jan,	100
Bob,	London,	Feb,	200
Bob,	London,	Mar,	300
Kate,	New York,	Jan,	400
Kate,	New York,	Feb,	500
Kate,	New York,	Mar,	600

Crosstable wizard

The crosstable wizard is dialog driven method of creating the crosstable statement. This dialog is opened by clicking the **Crosstable** button in the **Options** page of the **File Wizard**. The crosstable wizard contains the following options:

Crosstable Wizard fields

Field type	Description
Qualifier Fields	The number of qualifier fields that precede the fields to be transformed.
Attribute Field	The name of the new field that will contain all the fields (attribute values) to be transformed.
Data Field	The name of the new field that will contain the data of the attribute values.

First

The **First** prefix to a **LOAD** or **SELECT (SQL)** statement is used for loading a set maximum number of records from a data source table.

Syntax:

```
First n ( loadstatement | selectstatement )
```

Arguments:

First arguments

Argument	Description
n	An arbitrary expression that evaluates to an integer indicating the maximum number of records to be read. <i>n</i> can be enclosed in parentheses, like (<i>n</i>), but this is not required.

Examples:

```
First 10 LOAD * from abc.csv;
First (1) SQL SELECT * from Orders;
```

Generic

The **generic** prefix unpacks a tall table, creating one field per attribute value. This is similar to pivoting a table, except that it results in a separate table per field created.

Syntax:

```
Generic( loadstatement | selectstatement )
```

Tables loaded through a **generic** statement are not auto-concatenated.

Example:

```
Table1:
Generic LOAD * INLINE;
[
Key, Attribute, Value
Bob, Jan, 100
Bob, Feb, 200
Bob, Mar, 300
Kate, Jan, 400
Kate, Feb, 500
Kate, Mar, 600
];
```

Result:

This will result in 3 tables:

Table1.Jan:

Example 1

Key,	Jan
Bob,	100
Kate,	400

Table1.Feb:

Example 2

Key,	Feb
Bob,	200
Kate,	500

Table1.Mar:

Example 3

Key,	Mar
Bob,	300
Kate,	600

Hierarchy

The **hierarchy** prefix is used to transform a parent-child hierarchy table to a table that is useful in a QlikView data model. It can be put in front of a **LOAD** or a **SELECT** statement and will use the result of the loading statement as input for a table transformation.

The prefix creates an expanded nodes table, which normally has the same number of records as the input table, but in addition each level in the hierarchy is stored in a separate field. The path field can be used in a tree structure.

Syntax:

```
Hierarchy (NodeID, ParentID, NodeName, [ParentName, [ParentSource, [PathName, [PathDelimiter, Depth]]]]) (loadstatement | selectstatement)
```

The input table must be an adjacent nodes table. Adjacent nodes tables are tables where each record corresponds to a node and has a field that contains a reference to the parent node. In such a table the node is stored on one record only but the node can still have any number of children. The table may of course contain additional fields describing attributes for the nodes.

Usually the input table has exactly one record per node and in such a case the output table will contain the same number of records. However, sometimes there are nodes with multiple parents, i.e. one node is represented by several records in the input table. If so, the output table may have more records than the input table.

All nodes with a parent id not found in the node id column (including nodes with missing parent id) will be considered as roots. Also, only nodes with a connection to a root node - direct or indirect - will be loaded, thus avoiding circular references.

Additional fields containing the name of the parent node, the path of the node and the depth of the node can be created.

Arguments:

Hierarchy arguments

Argument	Description
NodeID	The name of the field that contains the node id. This field must exist in the input table.
ParentID	The name of the field that contains the node id of the parent node. This field must exist in the input table.
NodeName	The name of the field that contains the name of the node. This field must exist in the input table.
ParentName	A string used to name the new ParentName field. If omitted, this field will not be created.
ParentSource	The name of the field that contains the name of the node used to build the node path. Optional parameter. If omitted, NodeName will be used.
PathName	A string used to name the new Path field, which contains the path from the root to the node. Optional parameter. If omitted, this field will not be created.
PathDelimiter	A string used as delimiter in the new Path field. Optional parameter. If omitted, '\' will be used.
Depth	A string used to name the new Depth field, which contains the depth of the node in the hierarchy. Optional parameter. If omitted, this field will not be created.

Example:

```
Hierarchy(NodeID, ParentID, NodeName, ParentName, NodeName, PathName, '\', Depth) LOAD *
inline [
NodeID, ParentID, NodeName
1, 4, London
2, 3, Munich
3, 5, Germany
4, 5, UK
5, , Europe
];
```

Result:

Example 1

Node ID	NodeName	ParentID	ParentName	NodeName1	NodeName2	NodeName3	PathName	Depth
5	Europe		-	Europe	-	-	Europe	1
3	Germany	5	Europe	Europe	Germany	-	Europe\Germany	2
2	Munich	3	Germany	Europe	Germany	Munich	Europe\Germany\Munich	3

4	UK	5	Europe	Europe	UK	-	Europe\UK	2
1	London	4	UK	Europe	UK	London	Europe\UK\London	3

HierarchyBelongsTo

This prefix is used to transform a parent-child hierarchy table to a table that is useful in a QlikView data model. It can be put in front of a **LOAD** or a **SELECT** statement and will use the result of the loading statement as input for a table transformation.

The prefix creates a table containing all ancestor-child relations of the hierarchy. The ancestor fields can then be used to select entire trees in the hierarchy. The output table in most cases contains several records per node.

Syntax:

```
HierarchyBelongsTo (NodeID, ParentID, NodeName, AncestorID, AncestorName, [DepthDiff]) (loadstatement | selectstatement)
```

The input table must be an adjacent nodes table. Adjacent nodes tables are tables where each record corresponds to a node and has a field that contains a reference to the parent node. In such a table the node is stored on one record only but the node can still have any number of children. The table may of course contain additional fields describing attributes for the nodes.

An additional field containing the depth difference of the nodes can be created.

Arguments:

HierarchyBelongsTo arguments

Argument	Description
NodeID	The name of the field that contains the node id. This field must exist in the input table.
ParentID	The name of the field that contains the node id of the parent node. This field must exist in the input table.
NodeName	The name of the field that contains the name of the node. This field must exist in the input table.
AncestorID	A string used to name the new ancestor id field, which contains the id of the ancestor node.
AncestorName	A string used to name the new ancestor field, which contains the name of the ancestor node.
DepthDiff	A string used to name the new DepthDiff field, which contains the depth of the node in the hierarchy relative the ancestor node. Optional parameter. If omitted, this field will not be created.

Example:

```
HierarchyBelongsTo (NodeID, AncestorID, NodeName, AncestorID, AncestorName, DepthDiff) LOAD *
inline [
NodeID, AncestorID, NodeName
1, 4, London
2, 3, Munich
3, 5, Germany
4, 5, UK
5, , Europe
];
```

Result:

Example 1

NodeID	AncestorID	NodeName	AncestorName	DepthDiff
1	1	London	London	0
1	4	London	UK	1
1	5	London	Europe	2
2	2	Munich	Munich	0
2	3	Munich	Germany	1
2	5	Munich	Europe	2
3	3	Germany	Germany	0
3	5	Germany	Europe	1
4	4	UK	UK	0
4	5	UK	Europe	1
5	5	Europe	Europe	0

Image_Size

This clause is used with the **Info** prefix or the **Bundle** prefix to resize images from a database management system to fit in the fields.

Syntax:

```
Bundle [Image_Size (width,height )] ( loadstatement | selectstatement )
```

Arguments:

Image_Size arguments

Argument	Description
width	The width of the image specified in pixels.
height	The height of the image specified in pixels.

Example:

A thumbnail for each image in the folder *MyPictures* will be stored in the QlikView document. The images keep their width and height ratio.

```
for each vBundleExt in 'jpg', 'jpeg', 'jpe', 'png', 'jif', 'jfi'
for each vBundleFoundFile in filelist( GetFolderPath('MyPictures') & '\*.' & vBundleExt )
BundleFileList:
BUNDLE IMAGE_SIZE(20, 20) Info Load FileLongName, FileLongName;
Load @1:n as FileLongName Inline "$(vBundleFoundFile)" (fix, no labels);
Next vBundleFoundFile
Next vBundleExt
```

Info

The **info** prefix is used to link external information, such as a text file, a picture or a video to a field value.

Syntax:

```
Info( loadstatement | selectstatement )
```

If a piece of external information, such as a text file, a picture or a video is to be linked to a field value, this is done in a table that is loaded using an **info** prefix. (In some cases it will be preferable to store the information inside the QlikView file, by using the **bundle** prefix. The table must contain two columns only, the first one with the field values that will form the keys to the information, the second one containing the information elements, that is, the file names of the pictures etcetera.

The same applies to, for example, a picture from a database management system. On a binary field, a blob, the info select statement makes an implicit **bundle**, i.e. the binary data will be fetched immediately and stored in the QlikView file. The binary data must be the second field in a **SELECT** statement.

Example:

```
Info LOAD * inline[
LinkedField, ImageFileName
QlikView, QlikViewLogo.png
];
```

Result:

Only **LinkedField** will be visible as a field name.

If you add a text object to the sheet with representation set to **Image**, and enter the text =Info(LinkedField), the text object will show the image file name.

Inner

The **join** and **keep** prefixes can be preceded by the prefix **inner**. If used before **join** it specifies that an inner join should be used. The resulting table will thus only contain combinations of field values from the raw data tables where the linking field values are represented in both tables. If used before **keep**, it specifies that both raw data tables should be reduced to their common intersection before being stored in QlikView.

Syntax:

```
Inner ( Join | Keep ) [ (tablename) ] (loadstatement |selectstatement )
```

Arguments:

Table load arguments

Argument	Description
tablename	The named table to be compared to the loaded table.
loadstatement or selectstatement	The LOAD or SELECT statement for the loaded table.

Example 1:

Table1	-
A	B
1	aa
2	cc
3	ee

Table2	-
A	C
1	xx
4	yy

```
QVTable:
SQL SELECT * From table1;
inner join SQL SELECT * From table2;
```

QVTable	-	-
A	B	C
1	aa	xx

Example 2:

```
QVTab1:
SQL SELECT * From Table1;
QVTab2:
inner keep SQL SELECT * From Table2;
```

QVTab1	-
A	B
1	aa

QVTab2	-
A	C
1	xx

The two tables in the **keep** example are, of course, associated via A.

Inputfield

A field may be flagged as an input field by listing it in an **inputfield** statement before it is referenced in any **LOAD** or **SELECT** statements.

Key fields cannot be flagged as input fields.

inputfield fieldlist

fieldlist is a comma separated list of the fields that should be flagged as input fields. The wildcard characters * and ? are allowed in field names. Quoting of field names may be necessary when wildcards are used.

Input fields behave somewhat differently from regular fields. The most important difference is their ability to accept changes in field values, interactively or programmatically, without running the script. Field values must be loaded into the field via **LOAD** or **SELECT** statements. Each field value loaded in the script will create a placeholder for a field value replacement value. Only existing field values can thus be changed interactively or programmatically. The replacement value is user dependent, i.e. when an input field is used on a server, different users will see different sets of input field values. In input fields all field values will be treated as distinct, regardless if several have the same value. Input fields normally retain their previously set value after a reload.

Example 1:

```
Inputfield B;
Inputfield A,B;
Inputfield B??x*;
```

Example 2:

```
Inputfield I;Load RecNo() as I, RecNo() as K autogenerate 10;
```

The values in K need to be unique to allow I to be an input field.

IntervalMatch

The **IntervalMatch** prefix is used to create a table matching discrete numeric values to one or more numeric intervals, and optionally matching the values of one or several additional keys.

Syntax:

```
IntervalMatch (matchfield)(loadstatement | selectstatement )
IntervalMatch (matchfield,keyfield1 [ , keyfield2, ... keyfield5 ] )
(loadstatement | selectstatement )
```

The **IntervalMatch** prefix must be placed before a **LOAD** or a **SELECT** statement that loads the intervals. The field containing the discrete data points (Time in the example below) and additional keys must already have been loaded into QlikView before the statement with the **IntervalMatch** prefix. The prefix does not by itself read this field from the database table. The prefix transforms the loaded table of intervals and keys to a table that contains an additional column: the discrete numeric data points. It also expands the number of records so that the new table has one record per possible combination of discrete data point, interval and value of the key field(s).

The intervals may be overlapping and the discrete values will be linked to all matching intervals.

The extended **IntervalMatch** prefix is used to create a table matching discrete numeric values to one or more numeric intervals, while at the same time matching the values of one or several additional keys. This is a very powerful and flexible feature that can be used for linking transactions with dimensions that are changing over time: Slowly changing dimensions.

In order to avoid undefined interval limits being disregarded, it may be necessary to allow NULL values to map to other fields that constitute the lower or upper limits to the interval. This can be handled by the **NullAsValue** statement or by an explicit test that replaces NULL values with a numeric value well before or after any of the discrete numeric data points.

Arguments:

IntervalMatch arguments

Argument	Description
matchfield	The field containing the discrete numeric values to be linked to intervals.
keyfield	Fields that contain the additional attributes that are to be matched in the transformation.
loadstatementor selectstatement	Must result in a table, where the first field contains the lower limit of each interval, the second field contains the upper limit of each interval, and in the case of using key matching, the third and any subsequent fields contain the keyfield(s) present in the IntervalMatch statement. The intervals are always closed, i.e. the end points are included in the interval. Non-numeric limits render the interval to be disregarded (undefined).

Example 1:

In the two tables below, the first one defines the start and end times for the production of different orders. The second one lists a number of discrete events. By means of the **IntervalMatch** prefix it is possible to logically connect the two tables in order to find out e.g. which orders were affected by disturbances and which orders were processed by which shifts.

EventLog:

```
LOAD * Inline [
```

```
Time, Event, Comment
00:00, 0, Start of shift 1
01:18, 1, Line stop
02:23, 2, Line restart 50%
```

9 Script syntax and chart functions

```
04:15, 3, Line speed 100%
08:00, 4, Start of shift 2
11:43, 5, End of production
];
```

```
OrderLog:
LOAD * INLINE [
Start, End, Order
01:00, 03:35, A
02:30, 07:58, B
03:04, 10:27, C
07:23, 11:43, D
];
```

//Link the field Time to the time intervals defined by the fields Start and End.

```
Inner Join IntervalMatch ( Time )
```

```
LOAD Start, End
Resident OrderLog;
```

Result:

The table **OrderLog** contains now an additional column: *Time*. The number of records is also expanded.

Example 1

Time	Start	End	Order
00:00	-	-	-
01:18	01:00	03:35	A
02:23	01:00	03:35	A
04:15	02:30	07:58	B
04:15	03:04	10:27	C
08:00	03:04	10:27	C
08:00	07:23	11:43	D
11:43	07:23	11:43	D

Example 2: (using keyfield)

Same example than above, adding *ProductionLine* as a key field.

```
EventLog:
LOAD * Inline [
Time, Event, Comment, ProductionLine
00:00, 0, Start of shift 1, P1
01:00, 0, Start of shift 1, P2
01:18, 1, Line stop, P1
02:23, 2, Line restart 50%, P1
04:15, 3, Line speed 100%, P1
08:00, 4, Start of shift 2, P1
09:00, 4, Start of shift 2, P2
```

```
11:43, 5, End of production, P1
11:43, 5, End of production, P2
];
```

```
OrderLog:
LOAD * INLINE [
Start, End, Order, ProductionLine
01:00, 03:35, A, P1
02:30, 07:58, B, P1
03:04, 10:27, C, P1
07:23, 11:43, D, P2
];
```

```
//Link the field Time to the time intervals defined by the fields Start and End and match the
values
// to the key ProductionLine.
Inner Join
IntervalMatch ( Time, ProductionLine )
LOAD Start, End, ProductionLine
Resident OrderLog;
```

Result:

A table box could now be created as below:

Example 2

ProductionLine	Time	Event	Comment	Order	Start	End
P1	00:00	0	Start of shift 1	-	-	-
P2	01:00	0	Start of shift 1	-	-	-
P1	01:18	1	Line stop	A	01:00	03:35
P1	02:23	2	Line restart 50%	A	01:00	03:35
P1	04:15	3	Line speed 100%	B	02:30	07:58
P1	04:15	3	Line speed 100%	C	03:04	10:27
P1	08:00	4	Start of shift 2	C	03:04	10:27
P2	09:00	4	Start of shift 2	D	07:23	11:43
P1	11:43	5	End of production	-	-	-
P2	11:43	5	End of production	D	07:23	11:43

IntervalMatch (Extended Syntax)

The extended **IntervalMatch** prefix is used to create a table matching discrete numeric values to one or more numeric intervals, while at the same time matching the values of one or several additional keys.

This is a very powerful and flexible feature that can be used for linking transactions with dimensions that are changing over time: Slowly changing dimensions.

The **IntervalMatch** prefix must be placed before a **Load** or **Select** statement that loads the intervals. The table containing the discrete data points and the additional keys must already have been loaded into QlikView before the statement with the **IntervalMatch** prefix. The prefix transforms the loaded table of

9 Script syntax and chart functions

intervals and keys to a table that contains an additional column: the discrete numeric data points. It also expands the number of records so that the new table has one record per possible combination of discrete data point, interval and value of the key field(s).

The syntax is:

```
intervalmatch (matchfield, keyfield1 [ , keyfield2, ... keyfield5 ] )  
(loadstatement | selectstatement )
```

`matchfield` is the field containing the discrete numeric values to be linked to intervals.

`keyfield(s)` are fields that contain the additional attributes that are to be matched in the transformation.

`loadstatement` or `selectstatement` must result in a table where the first two fields contain the lower and upper limits of each interval and the third and any subsequent fields contain the `keyfield(s)` present in the **IntervalMatch** statement. The intervals are always closed, i.e. the end points are included in the interval. Non-numeric limits render the interval to be disregarded (undefined).

In order to avoid undefined interval limits being disregarded, it may be necessary to allow NULL values to map to other fields that constitute the lower or upper limits to the interval. This can be handled by the **NullAsValue** statement or by an explicit test that replaces NULLs with a numeric value well before or after any of the discrete numeric data points.

Example:

```
Inner Join IntervalMatch (Date,Key) LOAD FirstDate, LastDate, Key resident Key;
```

Join

The **join** prefix joins the loaded table with an existing named table or the last previously created data table.

Syntax:

```
[inner | outer | left | right ]Join [ (tablename ) ]( loadstatement |  
selectstatement )
```

The join is a natural join made over all the common fields. The join statement may be preceded by one of the prefixes **inner**, **outer**, **left** or **right**.

Arguments:

Table load arguments	
Argument	Description
tablename	The named table to be compared to the loaded table.
loadstatement or selectstatement	The LOAD or SELECT statement for the loaded table.

Example:

```
Join LOAD * from abc.csv;
```

```
Join SELECT * from table1;
```

```
tab1:
LOAD * from file1.csv;
tab2:
LOAD * from file2.csv;
... ..
join (tab1) LOAD * from file3.csv;
```

Keep

The **keep** prefix is similar to the **join** prefix. Just as the **join** prefix, it compares the loaded table with an existing named table or the last previously created data table, but instead of joining the loaded table with an existing table, it has the effect of reducing one or both of the two tables before they are stored in QlikView, based on the intersection of table data. The comparison made is equivalent to a natural join made over all the common fields, i.e. the same way as in a corresponding join. However, the two tables are not joined and will be kept in QlikView as two separately named tables.

Syntax:

```
(inner | left | right) keep [(tablename) ]( loadstatement | selectstatement )
```

The **keep** prefix must be preceded by one of the prefixes **inner**, **left** or **right**.

The explicit **join** prefix in QlikView script language performs a full join of the two tables. The result is one table. In many cases such joins will result in very large tables. One of the main features of QlikView is its ability to make associations between multiple tables instead of joining them, which greatly reduces memory usage, increases processing speed and offers enormous flexibility. Explicit joins should therefore generally be avoided in QlikView scripts. The keep functionality was designed to reduce the number of cases where explicit joins needs to be used.

Arguments:

Table load arguments

Argument	Description
tablename	The named table to be compared to the loaded table.
loadstatement or selectstatement	The LOAD or SELECT statement for the loaded table.

Example:

```
Inner Keep LOAD * from abc.csv;
Left Keep SELECT * from table1;
tab1:
LOAD * from file1.csv;
tab2:
LOAD * from file2.csv;
... ..
Left Keep (tab1) LOAD * from file3.csv;
```

Left

The **Join** and **Keep** prefixes can be preceded by the prefix **left**.

9 Script syntax and chart functions

If used before **join** it specifies that a left join should be used. The resulting table will only contain combinations of field values from the raw data tables where the linking field values are represented in the first table. If used before **keep**, it specifies that the second raw data table should be reduced to its common intersection with the first table, before being stored in QlikView.

Were you looking for the string function by the same name? See: [Left](#) (page 1552)

Syntax:

```
Left ( Join | Keep ) [ (tablename) ] (loadstatement | selectstatement)
```

Arguments:

Table load arguments

Argument	Description
tablename	The named table to be compared to the loaded table.
loadstatement or selectstatement	The LOAD or SELECT statement for the loaded table.

Example:

Example 1A

Table1	-
A	B
1	aa
2	cc
3	ee

Example 1B

Table2	-
A	C
1	xx
4	yy

QVTable:

```
SELECT * From table1;  
Left Join Select * From table2;
```

Example 1C

QVTable	-	-
A	B	C
1	aa	xx

9 Script syntax and chart functions

2	cc	
3	ee	

```
QVTab1:
SELECT * From Table1;
QVTab2:
Left Keep SELECT * From Table2;
```

Example 1D

QVTab1		-
A		B
1		aa
2		cc
3		ee

Example 1E

QVTab2		-
A		C
1		xx

The two tables in the **keep** example are, of course, associated via A.

```
tab1:
LOAD * From file1.csv;
tab2:
LOAD * From file2.csv;
.. .. .
Left Keep (tab1) LOAD * From file3.csv;
```

Mapping

The **mapping** prefix is used to create a mapping table that can be used to, for example, replacing field values and field names during script execution.

Syntax:

```
Mapping( loadstatement | selectstatement )
```

The **mapping** prefix can be put in front of a **LOAD** or a **SELECT** statement and will store the result of the loading statement as a mapping table. Mapping provides an efficient way to substituting field values during script execution, e.g. replacing US, U.S. or America with USA. A mapping table consists of two columns, the first containing comparison values and the second containing the desired mapping values. Mapping tables are stored temporarily in memory and dropped automatically after script execution.

The content of the mapping table can be accessed using e.g. the **Map ... Using** statement, the **Rename Field** statement, the **Applymap()** function or the **Mapsubstring()** function.

Example:

In this example we load a list of salespersons with a country code representing their country of residence. We use a table mapping a country code to a country to replace the country code with the country name. Only three countries are defined in the mapping table, other country codes are mapped to 'Rest of the world'.

```
// Load mapping table of country codes:
map1:
mapping LOAD *
inline [
CCode, Country
Sw, Sweden
Dk, Denmark
No, Norway
] ;

// Load list of salesmen, mapping country code to country
// If the country code is not in the mapping table, put Rest of the world
Salespersons:
LOAD *,
ApplyMap('map1', CCode, 'Rest of the world') As Country
inline [
CCode, Salesperson
Sw, John
Sw, Mary
Sw, Per
Dk, Preben
Dk, Olle
No, Ole
Sf, Risttu] ;
// We don't need the CCode anymore
Drop Field 'CCode';
```

The resulting table looks like this:

Example 1	
Salesperson	Country
John	Sweden
Mary	Sweden
Per	Sweden
Preben	Denmark
Olle	Denmark
Ole	Norway
Risttu	Rest of the world

Merge

The **Merge** prefix can be added to any **LOAD** or **SELECT** statement in the script to specify that the loaded table should be merged into another table. It also specifies that this statement should be run in a partial reload.

The typical use case is when you load a change log and want to use this to apply inserts, updates, and deletes to an existing table.

Syntax:

```
Merge [only] [(SequenceNoField [, SequenceNoVar])] On ListOfKeys [Concatenate [(TableName)]] (loadstatement | selectstatement)
```

During a normal (non-partial) reload, the **Merge LOAD** construction will work as a normal **Load** statement but with the additional functionality of removing older obsolete records and records marked for deletion. The first field of the load statement must hold information about the operation: Insert, Update, or Delete.

For each loaded record, the record identifier will be compared with previously loaded records, and only the latest record (according to the sequence number) will be kept. If the latest record is marked with Delete, none will be kept.

If the **Concatenate** prefix is used, or if there already exists a table with the same set of fields, this will be the relevant table to modify. Otherwise, the result of the **Merge LOAD** construction will be stored in a new table.

If the **Concatenate** prefix is used, the resulting table may have more fields than the change log that is used as input to the **Merge**.

A partial reload will do the same as a full reload. The only difference is that the **Merge LOAD** construction will never create a new table. There always exists a relevant table from the previous script execution to modify.

If the loaded change log is an accumulated log, that is it contains changes that already have been loaded, the parameter `SequenceNoVar` can be used in a **Where** clause to limit the amount of input data. The **Merge LOAD** could then be made to only load records where the field `SequenceNoField` is greater than `SequenceNoVar`. Upon completion, the **Merge LOAD** will assign a new value to the `SequenceNoVar` with the maximum value seen in the `SequenceNoField` field.

Arguments:

Arguments

Argument	Description
only	An optional qualifier denoting that the statement should be executed only during partial reloads. It should be disregarded during normal (non-partial) reloads.

Argument	Description
SequenceNoField	The name of the field containing a timestamp or a sequence number that defines the order of the operations.
SequenceNoVar	The name of the variable that gets assigned the maximum value for SequenceNoField of the table being merged.
ListOfKeys	A comma separated list of field names specifying the primary key.
operation	The first field of the load statement must contain the operation: Insert, Update, or Delete. 'i', 'u' and 'd' are also accepted.

NoConcatenate

The **NoConcatenate** prefix forces two loaded tables with identical field sets to be treated as two separate internal tables, when they would otherwise be automatically concatenated.

Syntax:

```
NoConcatenate ( loadstatement | selectstatement )
```

Example:

```
LOAD A,B from file1.csv;
NoConcatenate LOAD A,B from file2.csv;
```

Outer

The explicit **Join** prefix can be preceded by the prefix **outer** in order to specify an outer join. In an outer join all combinations between the two tables are generated. The resulting table will thus contain combinations of field values from the raw data tables where the linking field values are represented in one or both tables.

The **outer** keyword is optional and is the default join type used when a join prefix is not specified.

Syntax:

```
Outer Join [ (tablename) ] (loadstatement |selectstatement )
```

Arguments:

Table load arguments	
Argument	Description
tablename	The named table to be compared to the loaded table.
loadstatement or selectstatement	The LOAD or SELECT statement for the loaded table.

Example:

Example 1A

Table1	
	-
A	B

9 Script syntax and chart functions

1	aa
2	cc
3	ee

Example 1B

Table2	-
A	C
1	xx
4	yy

```
SQL SELECT * from table1;  
join SQL SELECT * from table2;  
OR
```

```
SQL SELECT * from table1;  
outer join SQL SELECT * from table2;
```

Example 1C

Joined table	-	-
A	B	C
1	aa	xx
2	cc	-
3	ee	-
4	-	yy

Partial reload

A normal (non-partial) reload always starts by deleting all tables in the existing data model, and then runs the load script.

A partial reload will not do this. Instead it keeps all tables in the data model and then executes only **Load** and **Select** statements preceded by an **Add**, **Merge**, or **Replace** prefix. Other data tables are not affected by the command. The **only** argument denotes that the statement should be executed only during partial reloads, and should be disregarded during normal (non-partial) reloads.

Replace

The **Replace** prefix can be added to any **LOAD** or **SELECT** statement in the script to specify that the loaded table should replace another table. It also specifies that this statement should be run in a partial reload. The **Replace** prefix can also be used in a **Map** statement.

Syntax:

```
Replace[only] [Concatenate [(tablename)]] (loadstatement | selectstatement)
```

```
Replace[only]mapstatement
```

During a normal (non-partial) reload, the **ReplaceLOAD** construction will work as a normal **LOAD** statement but be preceded by a **DropTable**. First the old table will be dropped, then records will be generated and stored as a new table.

If the **Concatenate** prefix is used, or if there exists a table with the same set of fields, this will be the relevant table to drop. Otherwise, there is no table to drop and the **ReplaceLOAD** construction will be identical to a normal **LOAD**.

A partial reload will do the same. The only difference is that there is always a table from the previous script execution to drop. The **ReplaceLOAD** construction will always first drop the old table, then create a new one.

The **Replace Map...Using** statement causes mapping to take place also during partial script execution.

Arguments:

Replace arguments

Argument	Description
only	An optional qualifier denoting that the statement should be disregarded during normal (non-partial) reloads.

Examples and results:

Examples and results

Example	Result
Tab1: Replace LOAD * from File1.csv;	During both normal and partial reload, the QlikView table Tab1 is initially dropped. Thereafter new data is loaded from File1.csv and stored in Tab1.
Tab1: Replace only LOAD * from File1.csv;	During normal reload, this statement is disregarded. During partial reload, any QlikView table previously named Tab1 is initially dropped. Thereafter new data is loaded from File1.csv and stored in Tab1.
Tab1: LOAD a,b,c from File1.csv; Replace LOAD a,b,c from File2.csv;	During normal reload, the file File1.csv is first read into the QlikView table Tab1, but then immediately dropped and replaced by new data loaded from File2.csv. All data from File1.csv is lost. During partial reload, the entire QlikView table Tab1 is initially dropped. Thereafter it is replaced by new data loaded from File2.csv.
Tab1: LOAD a,b,c from File1.csv; Replace only LOAD a,b,c from File2.csv;	During normal reload, data is loaded from File1.csv and stored in the QlikView table Tab1. File2.csv is disregarded. During partial reload, the entire QlikView table Tab1 is initially dropped. Thereafter it is replaced by new data loaded from File2.csv. All data from File1.csv is lost.

Right

The **Join** and **Keep** prefixes can be preceded by the prefix **right**.

If used before **join** it specifies that a right join should be used. The resulting table will only contain combinations of field values from the raw data tables where the linking field values are represented in the second table. If used before **keep**, it specifies that the first raw data table should be reduced to its common intersection with the second table, before being stored in QlikView.

Were you looking for the string function by the same name? See: Right (page 1556)

Syntax:

```
Right (Join | Keep) [(tablename)] (loadstatement | selectstatement )
```

Arguments:

Table load arguments

Argument	Description
tablename	The named table to be compared to the loaded table.
loadstatement or selectstatement	The LOAD or SELECT statement for the loaded table.

Example:

Example 1A

Table1	-
A	B
1	aa
2	cc
3	ee

Example 1B

Table2	-
A	C
1	xx
4	yy

QVTable:

```
SQL SELECT * from table1;
right join SQL SELECT * from table2;
```

9 Script syntax and chart functions

Example 1C

QVTable	-	-
A	B	C
1	aa	xx
4	-	yy

```
QVTab1:
SQL SELECT * from Table1;
QVTab2:
right keep SQL SELECT * from Table2;
```

Example 1D

QVTab1	-
A	B
1	aa

Example 1E

QVTab2	-
A	C
1	xx
4	yy

The two tables in the **keep** example are, of course, associated via A.

```
tab1:
LOAD * from file1.csv;
tab2:
LOAD * from file2.csv;
.. .. .
right keep (tab1) LOAD * from file3.csv;
```

Sample

The **sample** prefix to a **LOAD** or **SELECT** statement is used for loading a random sample of records from the data source.

Syntax:

```
Sample p ( loadstatement | selectstatement )
```

Arguments:

Sample arguments

Argument	Description
p	An arbitrary expression which evaluates to a number larger than 0 and lower or equal to 1. The number indicates the probability for a given record to be read. All records will be read but only some of them will be loaded into QlikView.

Example:

```
Sample 0.15 SQL SELECT * from Longtable;  
Sample(0.15) LOAD * from Longtab.csv;
```

The parentheses are allowed but not required.

Semantic

Tables containing relations between records can be loaded through a **semantic** prefix. This can for example be self-references within a table, where one record points to another, such as parent, belongs to, or predecessor.

Syntax:

```
Semantic( loadstatement | selectstatement )
```

The semantic load will create semantic fields that can be displayed in list boxes to be used for navigation in the data.

Tables loaded through a **semantic** statement cannot be concatenated.

Example:

```
Semantic LOAD * from abc.csv;  
Semantic SELECT Object1, Relation, Object2, InverseRelation from table1;
```

Unless

The **unless** prefix and suffix is used for creating a conditional clause which determines whether a statement or exit clause should be evaluated or not. It may be seen as a compact alternative to the full **if..end if** statement.

Syntax:

```
(Unless condition statement | exitstatement Unless condition )
```

The **statement** or the **exitstatement** will only be executed if **condition** is evaluated to False.

The **unless** prefix may be used on statements which already have one or several other statements, including additional **when** or **unless** prefixes.

Arguments:

Unless arguments

Argument	Description
condition	A logical expression evaluating to True or False.
statement	Any QlikView script statement except control statements.
exitstatement	An exit for , exit do or exit sub clause or an exit script statement.

Examples:

```
exit script unless A=1;
unless A=1 LOAD * from myfile.csv;
unless A=1 when B=2 drop table Tab1;
```

When

The **when** prefix and suffix is used for creating a conditional clause which determines whether a statement or exit clause should be executed or not. It may be seen as a compact alternative to the full **if..end if** statement.

Syntax:

```
(when condition statement | exitstatement when condition )
```

The **statement** or the **exitstatement** will only be executed if condition is evaluated to True.

The **when** prefix may be used on statements which already have one or several other statements, including additional **when** or **unless** prefixes.

Syntax:

When arguments

Argument	Description
condition	A logical expression evaluating to True or False.
statement	Any QlikView script statement except control statements.
exitstatement	An exit for , exit do or exit sub clause or an exit script statement.

Examples:

```
exit script when A=1;
when A=1 LOAD * from myfile.csv;
when A=1 unless B=2 drop table Tab1;
```

Script regular statements

Regular statements are typically used for manipulating data in one way or another. These statements may be written over any number of lines in the script and must always be terminated by a semicolon, ";".

All script keywords can be typed with any combination of lower case and upper case characters. Field and variable names used in the statements are however case sensitive.

Script regular statements overview

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

Alias

The **alias** statement is used for setting an alias according to which a field will be renamed whenever it occurs in the script that follows.

```
Alias fieldname as aliasname {,fieldname as aliasname}
```

AutoNumber

This statement creates a unique integer value for each distinct evaluated value in a field encountered during the script execution.

```
AutoNumber *fieldlist  
[Using namespace] ]
```

Binary

The **binary** statement is used for loading the data from another QlikView document, including section access data.

```
Binary [[path] filename]
```

Comment field

Provides a way of displaying the field comments (metadata) from databases and spreadsheets. Field names not present in the document will be ignored. If multiple occurrences of a field name are found, the last value is used.

```
Comment field *fieldlist using mapname  
Comment field fieldname with comment
```

Comment table

Provides a way of displaying the table comments (metadata) from databases or spreadsheets.

```
Comment table tablelist using mapname  
Comment table tablename with comment
```

Connect

The **CONNECT** statement is used to define QlikView access to a general database through the OLE DB/ODBC interface. For ODBC, the data source first needs to be specified using the ODBC administrator.

```
ODBC CONNECT TO connect-string  
OLEDB CONNECT TO connect-string  
CUSTOM CONNECT TO connect-string  
LIB CONNECT TO connection
```

Directory

The **Directory** statement defines which directory to look in for data files in subsequent **LOAD** statements, until a new **Directory** statement is made.

```
Directory [path]
```

Disconnect

The **Disconnect** statement terminates the current ODBC/OLE DB/Custom connection. This statement is optional.

```
Disconnect
```

drop field

One or several Qlik Sense fields can be dropped from the data model, and thus from memory, at any time during script execution, by means of a **drop field** statement. The "distinct" property of a table is removed after a **drop field** statement.

*Both **drop field** and **drop fields** are allowed forms with no difference in effect. If no table is specified, the field will be dropped from all tables where it occurs.*

```
Drop field fieldname [ , fieldname2 ...] [from tablename1 [ , tablename2 ...]]  
drop fields fieldname [ , fieldname2 ...] [from tablename1 [ , tablename2 ...]]
```

drop table

One or several QlikView internal tables can be dropped from the data model, and thus from memory, at any time during script execution, by means of a **drop table** statement.

*The forms **drop table** and **drop tables** are both accepted.*

```
Drop table tablename [, tablename2 ...]  
drop tables[ tablename [, tablename2 ...]]
```

Execute

The **Execute** statement is used to run other programs while QlikView is loading data. For example, to make conversions that are necessary.

```
Execute commandline
```

Force

The **force** statement forces QlikView to interpret field values of subsequent **LOAD** and **SELECT** statements as written with only upper case letters, with only lower case letters, as always capitalized or as they appear (mixed). This statement makes it possible to associate field values from tables made according to different conventions.

```
Force ( capitalization | case upper | case lower | case mixed )
```

LOAD

The **LOAD** statement loads fields from a file, from data defined in the script, from a previously loaded table, from a web page, from the result of a subsequent **SELECT** statement or by generating data automatically.

```
Load [ distinct ] *fieldlist  
[( from file [ format-spec ] |  
from_field fieldsource [format-spec]  
inline data [ format-spec ] |  
resident table-label |  
autogenerate size )]  
[ where criterion | while criterion ]  
[ group_by groupbyfieldlist ]  
[order_by orderbyfieldlist ]
```

Let

The **let** statement is a complement to the **set** statement, used for defining script variables. The **let** statement, in opposition to the **set** statement, evaluates the expression on the right side of the '=' before it is assigned to the variable.

```
Let variablename=expression
```

Loosen Table

One or more QlikView internal data tables can be explicitly declared loosely coupled during script execution by using a **Loosen Table** statement. The use of one or more **Loosen Table** statements in the script will make QlikView disregard any setting of tables as loosely coupled made before the script execution.

```
Loosen Table tablename [ , tablename2 ...]  
Loosen Tables tablename [ , tablename2 ...]
```

Map ... using

The **map ... using** statement is used for mapping a certain field value or expression to the values of a specific mapping table. The mapping table is created through the **Mapping** statement.

```
Map *fieldlist Using mapname
```

NullAsNull

The **NullAsNull** statement turns off the conversion of NULL values to string values previously set by a **NullAsValue** statement.

```
NullAsNull *fieldlist
```

NullAsValue

The **NullAsValue** statement specifies for which fields that NULL should be converted to a value.

```
NullAsValue *fieldlist
```

Qualify

The **Qualify** statement is used for switching on the qualification of field names, i.e. field names will get the table name as a prefix.

```
Qualify *fieldlist
```

Rem

The **rem** statement is used for inserting remarks, or comments, into the script, or to temporarily deactivate script statements without removing them.

```
Rem string
```

Rename Field

This script function renames one or more existing QlikView field(s) after they have been loaded.

```
Rename field (using mapname | oldname to newname{ , oldname to newname })
```

```
Rename Fields (using mapname | oldname to newname{ , oldname to newname })
```

Rename Table

This script function renames one or more existing QlikView internal table(s) after they have been loaded.

```
Rename table (using mapname | oldname to newname{ , oldname to newname })
```

```
Rename Tables (using mapname | oldname to newname{ , oldname to newname })
```

Section

With the **section** statement, it is possible to define whether the subsequent **LOAD** and **SELECT** statements should be considered as data or as a definition of the access rights.

```
Section (access | application)
```

Select

The selection of fields from an ODBC data source or OLE DB provider is made through standard SQL **SELECT** statements. However, whether the **SELECT** statements are accepted depends on the ODBC driver or OLE DB provider used.

```
Select [all | distinct | distinctrow | top n [percent] ] *fieldlist
```

```
From tablelist
```

```
[Where criterion ]
```

```
[Group by fieldlist [having criterion ] ]
```

```
[Order by fieldlist [asc | desc] ]
```

```
[ (Inner | Left | Right | Full)Join tablename on fieldref = fieldref ]
```

Set

The **set** statement is used for defining script variables. These can be used for substituting strings, paths, drives, and so on.

```
Set variablename=string
```

Sleep

The **sleep** statement pauses script execution for a specified time.

```
Sleep n
```

SQL

The **SQL** statement allows you to send an arbitrary SQL command through an ODBC or OLE DB connection.

```
SQL sql_command
```

SQLColumns

The **sqlcolumns** statement returns a set of fields describing the columns of an ODBC or OLE DB data source, to which a **connect** has been made.

```
SQLColumns
```

SQLTables

The **sqltables** statement returns a set of fields describing the tables of an ODBC or OLE DB data source, to which a **connect** has been made.

```
SQLTables
```

SQLTypes

The **sqltypes** statement returns a set of fields describing the types of an ODBC or OLE DB data source, to which a **connect** has been made.

```
SQLTypes
```

Star

The string used for representing the set of all the values of a field in the database can be set through the **star** statement. It affects the subsequent **LOAD** and **SELECT** statements.

```
Star is [ string ]
```

Store

This script function creates a QVD or a CSV file.

```
Store [ *fieldlist from] table into filename [ format-spec ];
```

Tag

This script function provides a way of assigning tags to one or more fields. If an attempt to tag a field name not present in the document is made, the tagging will be ignored. If conflicting occurrences of a field or tag name are found, the last value is used.

```
Tag fields fieldlist using mapname
```

```
Tag field fieldname with tagname
```

Trace

The **trace** statement writes a string to the **Script Execution Progress** window and to the script log file, when used. It is very useful for debugging purposes. Using **\$**-expansions of variables that are calculated prior to the **trace** statement, you can customize the message.

```
Trace string
```

Unmap

The **Unmap** statement disables field value mapping specified by a previous **Map ... Using** statement for subsequently loaded fields.

```
Unmap *fieldlist
```

Unqualify

The **Unqualify** statement is used for switching off the qualification of field names that has been previously switched on by the **Qualify** statement.

```
Unqualify *fieldlist
```

Untag

Provides a way of removing tags from one or more fields. If an attempt to untag a Field name not present in the document is made, the untagging will be ignored. If conflicting occurrences of a field or tag name is found, the last value is used.

```
Untag fields fieldlist using mapname
```

```
Untag field fieldname with tagname
```

Alias

The **alias** statement is used for setting an alias according to which a field will be renamed whenever it occurs in the script that follows.

Syntax:

```
alias fieldname as aliasname {,fieldname as aliasname}
```

Arguments:

Arguments

Argument	Description
fieldname	The name of the field in your source data
aliasname	An alias name you want to use instead

Examples with results

For the examples in the table below, the defined field name changes will be applied to references of the original field name on all subsequent **SELECT** and **LOAD** statements. A new alias can be defined for a field name by a new **alias** statement at any subsequent position in the script.

The field is also referenced with the alias name in the data model and app content.

Examples and results

Example	Result
Alias ID_N as NameID;	Field <i>ID_N</i> is renamed to <i>NameID</i> .
Alias A as Name, B as Number, C as Date;	Fields <i>A</i> , <i>B</i> , and <i>C</i> are renamed to <i>Name</i> , <i>Number</i> , and <i>Date</i> respectively.

Long-form example

Overview

Open the Data load editor and add the load script below to a new section.

Load script

```
alias [A] as [AAA];

T1:
Load 'string 1' as A autogenerated 1;
T2:
Load 'string 2' as B autogenerated 1;
T3:
Load 'string 3' as A autogenerated 1;
```

Results

Load the data and open a sheet. Create a new table and add this field as a dimension:

- AAA

Results
table

AAA
string 1
string 3

AutoNumber

This statement creates a unique integer value for each distinct evaluated value in a field encountered during the script execution.

You can also use the *autonumber* (page 1239) function inside a **LOAD** statement, but this has some limitations when you want to use an optimized load. You can create an optimized load by loading the data from a **QVD** file first, and then using the **AutoNumber** statement to convert values to symbol keys.

Syntax:

```
AutoNumber fieldlist [Using namespace] ]
```

Arguments:

Arguments

Argument	Description
fieldlist	<p>A comma-separated list of the fields where the values should be replaced by a symbol key.</p> <p>You can use wildcard characters ? and * in the field names to include all fields with matching names. You can also use * to include all fields. You need to quote field names when wildcards are used.</p>
namespace	<p>Using namespace is optional. You can use this option if you want to create a namespace, where identical values in different fields share the same key.</p> <p>If you do not use this option all fields will have a separate key index.</p>

Limitations:

When you have several **LOAD** statements in the script, you need to place the **AutoNumber** statement after the final **LOAD** statement.

Example:

In this example we replace field values with symbol table keys using the **AutoNumber** statement to conserve memory. The example is brief for demonstration purpose, but would be meaningful with a table containing a large number of rows.

Example data

Region	Year	Month	Sales
North	2014	May	245
North	2014	May	347
North	2014	June	127
South	2014	June	645
South	2013	May	367
South	2013	May	221

The source data is loaded using inline data. Then we add an **AutoNumber** statement with the Region, Year and Month fields.

```
RegionSales:
LOAD * INLINE
[ Region, Year, Month, Sales
North, 2014, May, 245
North, 2014, May, 347
North, 2014, June, 127
South, 2014, June, 645
```

```
South, 2013, May, 367  
South, 2013, May, 221  
];
```

```
AutoNumber Region, Year, Month;
```

The resulting table would look like this:

Results table

Region	Year	Month	Sales
1	2	1	245
1	2	1	347
1	2	2	127
2	2	2	645
2	1	1	367
2	1	1	221

Binary

The **binary** statement is used for loading the data from another QlikView document, including section access data. It does not load the layout information or variables.

We recommend that you only load data with the **binary** statement from documents with an optimized data model, that is, a data model that does not contain synthetic keys. If you load data from a document containing synthetic keys that only reference other synthetic keys, the entire data set may not be loaded.

Only one **binary** statement is allowed in the script. The **binary** statement must be the first statement of the script, even before the SET statements usually located at the beginning of the script.

Synthetic keys (page 142)

Syntax:

```
binary [[path] filename ]
```

Arguments:

Binary arguments

Argument	Description
path	<p>The path to the file, either absolute, or relative to the .qvw or .qvf file containing this script line. An absolute path is required if the file is not located in the QlikView path.</p> <ul style="list-style-type: none"> absolute <p>Example: <i>c:\data</i></p> <ul style="list-style-type: none"> relative to the document containing this script line. <p>Example: <i>data</i></p>
filename	<p>The name of the file, including the file extension .qvw or .qvf. If a file name is not supplied, the statement will load from the app itself. In other words, it will load from the app containing the binary statement.</p>

Examples and results:

Examples and results

Example	Result
<code>Binary ;</code>	This will load data from the app itself.
<code>Binary customer.qvw;</code>	In this example, <i>customer.qvw</i> must be in located in the QlikView working directory.
<code>Binary c:\qv\customer.qvw;</code>	This example uses an absolute file path.

Comment field

Provides a way of displaying the field comments (metadata) from databases and spreadsheets. Field names not present in the document will be ignored. If multiple occurrences of a field name are found, the last value is used.

Syntax:

```
comment [fields] *fieldlist using mapname
comment [field] fieldname with comment
```

The map table used should have two columns, the first containing field names and the second the comments.

Arguments:

Comment field arguments

Argument	Description
<i>*fieldlist</i>	A comma separated list of the fields to be commented. Using * as field list indicates all fields. The wildcard characters * and ? are allowed in field names. Quoting of field names may be necessary when wildcards are used.
<i>mapname</i>	The name of a mapping table previously read in a mapping LOAD or mapping SELECT statement.
<i>fieldname</i>	The name of the field that should be commented.
<i>comment</i>	The comment that should be added to the field.

Example 1:

```
commentmap:
mapping LOAD * inline [
a,b
Alpha,This field contains text values
Num,This field contains numeric values
];
comment fields using commentmap;
```

Example 2:

```
comment field Alpha with AFieldContainingCharacters;
comment field Num with '*A field containing numbers';
comment Gamma with 'Mickey Mouse field';
```

Comment table

Provides a way of displaying the table comments (metadata) from databases or spreadsheets.

Table names not present in the document are ignored. If multiple occurrences of a table name are found, the last value is used. The keyword can be used to read comments from a data source.

Syntax:

```
comment [tables] tablelist using mapname
comment [table] tablename with comment
```

Arguments:

Comment table arguments

Argument	Description
<i>tablelist</i>	(table{,table})

Argument	Description
<i>mapname</i>	The name of a mapping table previously read in a mapping LOAD or mapping SELECT statement.
<i>tablename</i>	The name of the table that should be commented.
<i>comment</i>	The comment that should be added to the table.

Example 1:

```
Commentmap:
mapping LOAD * inline [
a,b
Main,This is the fact table
Currencies, Currency helper table
];
comment tables using Commentmap;
```

Example 2:

```
comment table Main with 'Main fact table';
```

Connect

The **CONNECT** statement is used to define QlikView access to a general database through the OLE DB/ODBC interface. For ODBC, the data source first needs to be specified using the ODBC administrator.

Syntax:

```
ODBC CONNECT TO connect-string
OLEDB CONNECT TO connect-string
CUSTOM CONNECT TO connect-string
LIB CONNECT TO connection
```

Arguments:

Connect arguments

Argument	Description
connect-string	<p><code>connect-string ::= datasourcename { ; conn-spec-item }</code></p> <p>The connection string is the data source name and an optional list of one or more connection specification items. If the data source name contains blanks, or if any connection specification items are listed, the connection string must be enclosed by quotation marks.</p> <p>datasourcename must be a defined ODBC data source or a string that defines an OLE DB provider.</p> <p><code>conn-spec-item ::= DBQ=database_specifier DriverID=driver_specifier UID=userid PWD=password</code></p> <p>The possible connection specification items may differ between different databases. For some databases, also other items than the above are possible. For OLE DB, some of the connection specific items are mandatory and not optional.</p>
connection	The name of a data connection stored in the script editor.

If the **ODBC** is placed before **CONNECT**, the ODBC interface will be used; else, OLE DB will be used.

Using **LIB CONNECT TO** connects to a database using a stored data connection that was created in the script editor.

Example 1:

```
ODBC CONNECT TO 'Sales
DBQ=C:\Program Files\Access\Samples\Sales.mdb';
```

The data source defined through this statement is used by subsequent **Select (SQL)** statements, until a new **CONNECT** statement is made.

Example 2:

```
LIB CONNECT TO 'MyDataConnection';
```

Connect32

This statement is used the same way as the **CONNECT** statement, but forces a 64-bit system to use a 32-bit ODBC/OLE DB provider. Not applicable for custom connect.

Connect64

This statement is used the same way as the **CONNECT** statement, but forces use of a 64-bit provider. Not applicable for custom connect.

Directory

The **Directory** statement defines which directory to look in for data files in subsequent **LOAD** statements, until a new **Directory** statement is made.

Syntax:

```
Directory [path]
```

If the **Directory** statement is issued without a **path** or left out, QlikView will look in the QlikView working directory.

Arguments:

Argument	Description
path	<p>A text that can be interpreted as the path to the data file.</p> <p>The path is the path to the file, either:</p> <ul style="list-style-type: none">• absolute Example: c:\data• relative to the QlikView document path. Example: data• URL address (HTTP or FTP), pointing to a location on the Internet or an intranet. Example: http://www.qlik.com

Example:

```
DIRECTORY C:\userfiles\data; // OR -> DIRECTORY data\;
```

```
LOAD * FROM  
[data1.csv] // ONLY THE FILE NAME CAN BE SPECIFIED HERE (WITHOUT THE FULL PATH)  
(ansi, txt, delimiter is ',', embedded labels);
```

```
LOAD * FROM  
[data2.txt] // ONLY THE FILE NAME CAN BE SPECIFIED HERE UNTIL A NEW DIRECTORY STATEMENT IS  
MADE  
(ansi, txt, delimiter is '\t', embedded labels);
```

Disconnect

The **Disconnect** statement terminates the current ODBC/OLE DB/Custom connection. This statement is optional.

Syntax:

```
Disconnect
```

The connection will be automatically terminated when a new **connect** statement is executed or when the script execution is finished.

Example:

```
Disconnect;
```

Drop field

One or several Qlik Sense fields can be dropped from the data model, and thus from memory, at any time during script execution, by means of a **drop field** statement. The "distinct" property of a table is removed after a **drop field** statement.

*Both **drop field** and **drop fields** are allowed forms with no difference in effect. If no table is specified, the field will be dropped from all tables where it occurs.*

Syntax:

```
Drop field fieldname [ , fieldname2 ...] [from tablename1 [ , tablename2 ...]]
```

```
Drop fields fieldname [ , fieldname2 ...] [from tablename1 [ , tablename2 ...]]
```

Examples:

```
Drop field A;  
Drop fields A,B;  
Drop field A from X;  
Drop fields A,B from X,Y;
```

Drop table

One or several QlikView internal tables can be dropped from the data model, and thus from memory, at any time during script execution, by means of a **drop table** statement.

Syntax:

```
drop table tablename [ , tablename2 ...]
```

```
drop tables [ tablename [ , tablename2 ...]]
```

*The forms **drop table** and **drop tables** are both accepted.*

The following items will be lost as a result of this:

- The actual table(s).
- All fields which are not part of remaining tables.
- Field values in remaining fields, which came exclusively from the dropped table(s).

Examples and results:

Examples and results

Example	Result
<pre>drop table Orders, Salesmen, T456a;</pre>	This line results in three tables being dropped from memory.
<pre>Tab1: Load * Inline [Customer, Items, UnitPrice Bob, 5, 1.50]; Tab2: LOAD Customer, Sum(Items * UnitPrice) as Sales resident Tab1 group by Customer; drop table Tab1;</pre>	Once the table <i>Tab2</i> is created, the table <i>Tab1</i> is dropped.

Execute

The **Execute** statement is used to run other programs while QlikView is loading data. For example, to make conversions that are necessary.

Syntax:

```
execute commandline
```

Arguments:

Execute arguments

Argument	Description
<i>commandline</i>	A text that can be interpreted by the operating system as a command line.

Enable Execute in QlikView

By default, execution of **Execute** statements during reload is disabled both in QlikView Server and QlikView Desktop. You can manually enable the **Execute** command in QlikView Server or QlikView Desktop installations.

QlikView Server

You can enable **Execute** statements for QlikView Server by modifying the QlikView Batch *Settings.ini* file.

Do the following:

- Navigate to
C:\Windows\System32\config\systemprofile\AppData\Roaming\QlikTech\QlikViewBatch and open

the *Settings.ini* file.

- Locate the line `AllowExecuteCommand` and set the value to 1 as shown below:

```
AllowExecuteCommand=1
```

Now, when running the reload of the document from the QlikView Management Console, **Execute** statements are enabled.

The execution of an **Execute** statement is registered in the QlikView Batch (QVB) log file. To generate QlikView Batch log files when you run the script in QlikView Server, open the *Settings.ini* file located in `C:\Windows\System32\config\systemprofile\AppData\Roaming\QlikTech\QlikViewBatch` and add the following flag:

```
EnableQVBLog=1
```

QlikView Desktop

Do the following:

- On QlikView Desktop Start Page, click the **Settings** drop-down menu and select **Users Preferences...**
- On the **Security** tab, select **Script (Allow Database Write and Execute Statements)** to enable the security override.

The **Script (Allow Database Write and Execute Statements)** setting must always be enabled if you want to allow Execute statements in the script.

See: [User Preferences: Security](#)

- Open the QlikView document in which you want to perform the **Execute** statement, and open the **Script Editor** by selecting **Edit Script...** from the **File** drop-down menu.
- In the lower part of the Script Editor window, go to the **Settings** tab and select **Can Execute External Programs**.

Now, you can execute a statement in the script during reload.

It is possible to execute a statement during reload also if the setting **Can Execute External Programs** is not enabled in the Script Editor Settings. In this case, a **Security Alert** window appears every time you run a script containing an Execute statement. To allow the script to run the Execute statement, select **Override Security, Execute This Statement** from the options provided in the Security Alert window.

The execution of an Execute statement is registered in log files. To enable the generation of log files when you run the script in QlikView Desktop, select **Document Properties...** from the **Settings** drop-down menu, and select **Generate Logfile** on the **General** tab.

Example:

```
Execute "C:\Program Files\office12\Excel.exe";
```

```
Execute "winword macro.doc";  
Execute cmd.exe /C "C:\BatFiles\Log.bat";
```

/C needs to be included as it is a parameter to cmd.exe.

Force

The **force** statement forces QlikView to interpret field values of subsequent **LOAD** and **SELECT** statements as written with only upper case letters, with only lower case letters, as always capitalized or as they appear (mixed). This statement makes it possible to associate field values from tables made according to different conventions.

The **force** statement can also change field names during a load or select with the following data sources:

- QVD
- CSV (text files)
- XLS
- QVX (files and ODBC connections)

The **force** statement only changes field names if the data is loaded in compact mode (loaded with *).

The field names of the following data sources are not affected by the **force** statement:

- JSON
- Parquet
- XML
- XLSX

Syntax:

```
Force ( capitalization | case upper | case lower | case mixed )
```

If nothing is specified, force case mixed is assumed. The force statement is valid until a new force statement is made.

The **force** statement has no effect in the access section: all field values loaded are case insensitive.

Examples and results:

Examples and results

Example	Result
<p>This example shows how to force capitalization.</p> <pre>FORCE Capitalization; Capitalization: LOAD * Inline [ab Cd eF GH];</pre>	<p>The Capitalization table contains the following values:</p> <p>Ab Cd Ef Gh</p> <p>All values are capitalized.</p>
<p>This example shows how to force case upper.</p> <pre>FORCE Case Upper; CaseUpper: LOAD * Inline [ab Cd eF GH];</pre>	<p>The CaseUpper table contains the following values:</p> <p>AB CD EF GH</p> <p>All values are upper case.</p>
<p>This example shows how to force case lower.</p> <pre>FORCE Case Lower; CaseLower: LOAD * Inline [ab Cd eF GH];</pre>	<p>The CaseLower table contains the following values:</p> <p>ab cd ef gh</p> <p>All values are lower case.</p>
<p>This example shows how to force case mixed.</p> <pre>FORCE Case Mixed; CaseMixed: LOAD * Inline [ab Cd eF GH];</pre>	<p>The CaseMixed table contains the following values:</p> <p>ab Cd eF GH</p> <p>All values are as they appear in the script.</p>

Load

The **LOAD** statement loads fields from a file, from data defined in the script, from a previously loaded table, from a web page, from the result of a subsequent **SELECT** statement or by generating data automatically.

Syntax:

```
LOAD [ distinct ] fieldlist  
[( from file [ format-spec ] |  
from_field fieldsource [format-spec]  
inline data [ format-spec ] |  
resident table-label |  
autogenerate size )]  
[ where criterion | while criterion ]  
[ group_by groupbyfieldlist ]  
[order_by orderbyfieldlist ]
```

Arguments:

Load arguments

Argument	Description
distinct	<p>You can use distinct as a predicate if you only want to load unique records. If there are duplicate records, the first instance will be loaded.</p> <p>If you are using preceding loads, you need to place distinct in the first load statement, as distinct only affects the destination table.</p>

Argument	Description
fieldlist	<p><i>fieldlist</i> ::= (* field {, field })</p> <p>A list of the fields to be loaded. Using * as a field list indicates all fields in the table.</p> <p><i>field</i> ::= (<i>fieldref</i> <i>expression</i>) [as <i>aliasname</i>]</p> <p>The field definition must always contain a literal, a reference to an existing field, or an expression.</p> <p><i>fieldref</i> ::= (<i>fieldname</i> @<i>fieldnumber</i> @<i>startpos:endpos</i> [I U R B T])</p> <p><i>fieldname</i> is a text that is identical to a field name in the table. Note that the field name must be enclosed by straight double quotation marks or square brackets if it contains e.g. spaces. Sometimes field names are not explicitly available. Then a different notation is used:</p> <p>@<i>fieldnumber</i> represents the field number in a delimited table file. It must be a positive integer preceded by "@". The numbering is always made from 1 and up to the number of fields.</p> <p>@<i>startpos:endpos</i> represents the start and end positions of a field in a file with fixed length records. The positions must both be positive integers. The two numbers must be preceded by "@" and separated by a colon. The numbering is always made from 1 and up to the number of positions. In the last field, n is used as end position.</p> <ul style="list-style-type: none"> • If @<i>startpos:endpos</i> is immediately followed by the characters I or U, the bytes read will be interpreted as a binary signed (I) or unsigned (U) integer (Intel byte order). The number of positions read must be 1, 2 or 4. • If @<i>startpos:endpos</i> is immediately followed by the character R, the bytes read will be interpreted as a binary real number (IEEE 32-bit or 64 bit floating point). The number of positions read must be 4 or 8. • If @<i>startpos:endpos</i> is immediately followed by the character B, the bytes read will be interpreted as a BCD (Binary Coded Decimal) numbers according to the COMP-3 standard. Any number of bytes may be specified. <p><i>expression</i> can be a numeric function or a string function based on one or several other fields in the same table. For further information, see the syntax of expressions.</p> <p>as is used for assigning a new name to the field.</p>

Argument	Description
from	<p>from is used if data should be loaded from a file.</p> <p><i>file ::= [path] filename</i></p> <ul style="list-style-type: none"> • absolute <p style="margin-left: 20px;">Example: c:\data</p> <ul style="list-style-type: none"> • relative to the QlikView document path. <p style="margin-left: 20px;">Example: data</p> <ul style="list-style-type: none"> • URL address (HTTP or FTP), pointing to a location on the Internet or an intranet. The URL must be URL encoded, for example, if it contains space characters. <p style="margin-left: 20px;">Example: <i>http://www.qlik.com</i></p> <p style="margin-left: 20px;">Example: <i>http://www.enterprise.com/project%20files</i> (<i>http://www.enterprise.com/project files</i>)</p> <p>If the path is omitted, QlikView searches for the file in the directory specified by the Directory statement. If there is no Directory statement, QlikView searches in the working directory, which is usually the directory in which the QlikView file is located.</p> <div style="border: 1px solid #ccc; padding: 10px; margin: 10px 0;"> <p> <i>In a QlikView server installation, the default working directory is C:\ProgramData\QlikTech\Documents. The default working directory can be modified in the QlikView Management Console.</i></p> </div> <p>The <i>filename</i> may contain the standard DOS wildcard characters (* and ?). This will cause all the matching files in the specified directory to be loaded.</p> <p><i>format-spec ::= (fspec-item { , fspec-item })</i></p> <p>The format specification consists of a list of several format specification items, within brackets.</p>
from_field	<p>from_field is used if data should be loaded from a previously loaded field.</p> <p><i>fieldsource ::= (tablename, fieldname)</i></p> <p>The field is the name of the previously loaded <i>tablename</i> and <i>fieldname</i>.</p> <p><i>format-spec ::= (fspec-item { , fspec-item })</i></p> <p>The format specification consists of a list of several format specification items, within brackets.</p>

Argument	Description
inline	<p>inline is used if data should be typed within the script, and not loaded from a file. <i>data ::= [text]</i></p> <p>Data entered through an inline clause must be enclosed by specific characters - square brackets, quotation marks, or back ticks. The text between these is interpreted in the same way as the content of a file. Hence, where you would insert a new line in a text file, you should also do it in the text of an inline clause: by pressing the Enter key when typing the script.</p> <p>In a simple inline load, the number of columns are defined by the first line. <i>format-spec ::= (fspec-item {, fspec-item })</i></p> <p>You can customize the inline load with many of the same format specification items that are available for other loaded tables. These items are listed in brackets. For more information, see <i>Format specification items (page 960)</i>.</p> <p>For more information about inline loads, see <i>Loading data from inline tables (page 152)</i>.</p>
resident	<p>resident is used if data should be loaded from a previously loaded table. <i>table label</i> is a label preceding the LOAD or SELECT statement(s) that created the original table. The label should be given with a colon at the end.</p> <p>When using a combination of distinct and resident load statements in QlikView 12.00 or later, the data load order is different from QlikView 11.20. To define a desired load order, add a order by clause.</p>
autogenerate	<p>autogenerate is used if data should be automatically generated by QlikView. <i>size ::= number</i></p> <p><i>Number</i> is an integer indicating the number of records to be generated. The field list must not contain expressions which require data from a database. Only constants and parameter-free functions (such as <i>rand()</i> or <i>recno()</i>), are allowed in the expressions.</p>

Argument	Description
extension	<p>You can load data from analytic connections. You need to use the extension clause to call a function defined in the server-side extension (SSE) plugin, or evaluate a script.</p> <p>You can send a single table to the SSE plugin, and a single data table is returned. If the plugin does not specify the names of the fields that are returned, the fields will be named Field1, Field2, and so on.</p> <pre>Extension pluginname.functionname(tabledescription);</pre> <ul style="list-style-type: none"> • Loading data using a function in an SSE plugin <i>tabledescription ::= (table { ,tablefield})</i> If you do not state table fields, the fields will be used in load order. • Loading data by evaluating a script in an SSE plugin <i>tabledescription ::= (script, table { ,tablefield})</i> <p>Data type handling in the table field definition</p> <p>Data types are automatically detected in analytic connections. If the data has no numeric values and at least one non-NULL text string, the field is considered as text. In any other case it is considered as numeric.</p> <p>You can force the data type by wrapping a field name with String() or Mixed().</p> <ul style="list-style-type: none"> • String() forces the field to be text. If the field is numeric, the text part of the dual value is extracted, there is no conversion performed. • Mixed() forces the field to be dual. <p>String() or Mixed() cannot be used outside extension table field definitions, and you cannot use other QlikView functions in a table field definition.</p> <p>More about analytic connections</p> <p>For creating an analytic connection in QlikView Server or QlikView Desktop, see: Analytic connections</p>
where	<p>where is a clause used for stating whether a record should be included in the selection or not. The selection is included if <i>criterion</i> is True. <i>criterion</i> is a logical expression.</p>
while	<p>while is a clause used for stating whether a record should be repeatedly read. The same record is read as long as <i>criterion</i> is True. In order to be useful, a while clause must typically include the IteNo() function. <i>criterion</i> is a logical expression.</p>

Argument	Description
group_by	<p>group by is a clause used for defining over which fields the data should be aggregated (grouped). The aggregation fields should be included in some way in the expressions loaded. No other fields than the aggregation fields may be used outside aggregation functions in the loaded expressions.</p> <p><i>groupbyfieldlist ::= (fieldname { ,fieldname })</i></p>
order_by	<p>order by is a clause used for sorting the records of a resident table before they are processed by the load statement. The resident table can be sorted by one or more fields in ascending or descending order. The sorting is made primarily by numeric value and secondarily by national collation order. This clause may only be used when the data source is a resident table.</p> <p>The ordering fields specify which field the resident table is sorted by. The field can be specified by its name or by its number in the resident table (the first field is number 1).</p> <p><i>orderbyfieldlist ::= fieldname [sortorder] { , fieldname [sortorder] }</i></p> <p><i>sortorder</i> is either <i>asc</i> for ascending or <i>desc</i> for descending. If no <i>sortorder</i> is specified, <i>asc</i> is assumed.</p> <p><i>fieldname</i>, <i>path</i>, <i>filename</i> and <i>aliasname</i> are text strings representing what the respective names imply. Any field in the source table can be used as <i>fieldname</i>. However, fields created through the <i>as</i> clause (<i>aliasname</i>) are out of scope and cannot be used inside the same load statement.</p>

If no source of data is given by means of a **from**, **inline**, **resident**, **from_field** or **autogenerate** clause, data will be loaded from the result of the immediately succeeding **SELECT** or **LOAD** statement. The succeeding statement should not have a prefix.

Examples:

Loading different file formats

Load a delimited data file with default options:

```
LOAD * from data1.csv;
```

Load a delimited file, specifying comma as delimiter and with embedded labels:

```
LOAD * from 'c:\userfiles\data1.csv' (ansi, txt, delimiter is ',', embedded labels);
```

Load a delimited file specifying tab as delimiter and with embedded labels:

```
LOAD * from 'c:\userfiles\data2.txt' (ansi, txt, delimiter is '\t', embedded labels);
```

Load a dif file with embedded headers:

```
LOAD * from file2.dif (ansi, dif, embedded labels);
```

Load three fields from a fixed record file without headers:

9 Script syntax and chart functions

LOAD @1:2 as ID, @3:25 as Name, @57:80 as City from data4.fix (ansi, fix, no labels, header is 0, record is 80);

Load a QVX file, specifying an absolute path:

```
LOAD * from C:\qdssamples\xyz.qvx (qvx);
```

Selecting certain fields, renaming and calculating fields

Load only three specific fields from a delimited file:

```
LOAD FirstName, LastName, Number from data1.csv;
```

Rename first field as A and second field as B when loading a file without labels:

```
LOAD @1 as A, @2 as B from data3.txt (ansi, txt, delimiter is '\t', no labels);
```

Load Name as a concatenation of FirstName, a space character, and LastName:

```
LOAD FirstName & ' ' & LastName as Name from data1.csv;
```

Load Quantity, Price and Value (the product of Quantity and Price):

```
LOAD Quantity, Price, Quantity*Price as value from data1.csv;
```

Selecting certain records

Load only unique records, duplicate records will be discarded:

```
LOAD distinct FirstName, LastName, Number from data1.csv;
```

Load only records where the field Litres has a value above zero:

```
LOAD * from Consumption.csv where Litres>0;
```

Loading data not on file and auto-generated data

Load a table with inline data, two fields named CatID and Category:

```
LOAD * Inline  
[CatID, Category  
0,Regular  
1,Occasional  
2,Permanent];
```

Load a table with inline data, three fields named UserID, Password and Access:

```
LOAD * Inline [UserID, Password, Access  
A, ABC456, User  
B, VIP789, Admin];
```

Load a table with 10 000 rows. Field A will contain the number of the read record (1,2,3,4,5...) and field B will contain a random number between 0 and 1:

```
LOAD RecNo( ) as A, rand( ) as B autogenerate(10000);
```

The parenthesis after autogenerate is allowed but not required.

Loading data from a previously loaded table

First we load a delimited table file and name it tab1:

```
tab1:  
SELECT A,B,C,D from transtable;
```

Load fields from the already loaded tab1 table as tab2:

```
tab2:  
LOAD A,B,month(C),A*B+D as E resident tab1;
```

Load fields from already loaded table tab1 but only records where A is larger than B:

```
tab3:  
LOAD A,A+B+C resident tab1 where A>B;
```

Load fields from already loaded table tab1 ordered by A:

```
LOAD A,B*C as E resident tab1 order by A;
```

Load fields from already loaded table tab1, ordered by the first field, then the second field:

```
LOAD A,B*C as E resident tab1 order by 1,2;
```

Load fields from already loaded table tab1 ordered by C descending, then B in ascending order, and then the first field in descending order:

```
LOAD A,B*C as E resident tab1 order by C desc, B asc, 1 des;
```

Loading data from previously loaded fields

Load field Types from previously loaded table Characters as A:

```
LOAD A from_field (Characters, Types);
```

Loading data from a succeeding table (preceding load)

Load A, B and calculated fields X and Y from Table1 that is loaded in succeeding **SELECT** statement:

```
LOAD A, B, if(C>0,'positive','negative') as X, weekday(D) as Y;  
SELECT A,B,C,D from Table1;
```

Grouping data

Load fields grouped (aggregated) by ArtNo:

```
LOAD ArtNo, round(Sum(TransAmount),0.05) as ArtNoTotal from table.csv group by ArtNo;
```

Load fields grouped (aggregated) by Week and ArtNo:

```
LOAD week, ArtNo, round(Avg(TransAmount),0.05) as weekArtNoAverages from table.csv group by week, ArtNo;
```

Reading one record repeatedly

In this example we have a input file Grades.csv containing the grades for each student condensed in one field:

```
Student,Grades
Mike,5234
John,3345
Pete,1234
Paul,3352
```

The grades, in a 1-5 scale, represent subjects Math, English, Science and History. We can separate the grades into separate values by reading each record several times with a **while** clause, using the **IterNo()** function as a counter. In each read, the grade is extracted with the **Mid** function and stored in Grade, and the subject is selected using the **pick** function and stored in Subject. The final **while** clause contains the test to check if all grades have been read (four per student in this case), which means next student record should be read.

MyTab:

```
LOAD Student,
mid(Grades,IterNo(),1) as Grade,
pick(IterNo(), 'Math', 'English', 'Science', 'History') as Subject from Grades.csv
while IsNum(mid(Grades,IterNo(),1));
```

The result is a table containing this data:

Student	Subject	Grade
John	English	3
John	History	5
John	Math	3
John	Science	4
Mike	English	2
Mike	History	4
Mike	Math	5
Mike	Science	3
Paul	English	3
Paul	History	2
Paul	Math	3
Paul	Science	5
Pete	English	2
Pete	History	4
Pete	Math	1
Pete	Science	3

Loading from analytic connections

The following sample data is used.

values:

Load

```
Rand() as A,
```

```
Rand() as B,
```

```
Rand() as C
```

```
AutoGenerate(50);
```

Loading data using a function

In these examples, we assume that we have an analytic connection plugin named *P* that contains a custom function *Calculate(Parameter1, Parameter2)*. The function returns the table *Results* that contains the fields *Field1* and *Field2*.

```
Load * Extension P.Calculate( values{A, C} );
```

Load all fields that are returned when sending the fields A and C to the function.

```
Load Field1 Extension P.Calculate( values{A, C} );
```

Load only the Field1 field when sending the fields A and C to the function.

```
Load * Extension P.Calculate( Values );
```

Load all fields that are returned when sending the fields A and B to the function. As fields are not specified, A and B are used as they are the first in order in the table.

```
Load * Extension P.Calculate( values {C, C});
```

Load all fields that are returned when sending the field C to both parameters of the function.

```
Load * Extension P.Calculate( values {String(A), Mixed(B)});
```

Load all fields that are returned when sending the field A forced as a string and B forced as a numeric to the function.

Loading data by evaluating a script

```
Load A as A_echo, B as B_echo Extension R.ScriptEval( 'q;', values{A, B} );
```

Load the table returned by the script q when sending the values of A and B.

```
Load * Extension R.ScriptEval( '$(My_R_Script)', values{A, B} );
```

Load the table returned by the script stored in the My_R_Script variable when sending the values of A and B.

```
Load * Extension R.ScriptEval( '$(My_R_Script)', values{B as D, *} );
```

Load the table returned by the script stored in the My_R_Script variable when sending the values of B renamed to D, A and C. Using * sends the remaining unreferenced fields.

Format specification items

Each format specification item defines a certain property of the table file:

```
fspec-item ::= [ ansi | oem | mac | UTF-8 | Unicode | txt | fix | dif | biff | ooxml | html | xml | qvd | qvx  
| delimiter is char | no eof | embedded labels | explicit labels | no labels | table is [tablename] | header  
is n | header is line | header is n lines | comment is string | record is n | record is line | record  
is n lines | no quotes |msq ]
```

Character set

Character set is a file specifier for the **LOAD** statement that defines the character set used in the file.

Syntax:

```
utf8 | unicode | ansi | oem | mac | codepage is
```

Arguments:

Character set arguments

Argument	Description
utf8	UTF-8 character set
unicode	Unicode character set
ansi	Windows, codepage 1252
oem	DOS, OS/2, AS400 and others
mac	Codepage 10000
codepage is	With the codepage specifier, it is possible to use any Windows codepage as <i>N</i> .

Limitations:

Conversion from the **oem** character set is not implemented for macOS. If nothing is specified, codepage 1252 is assumed under Windows.

Example:

```
LOAD * from a.txt (utf8, txt, delimiter is ',' , embedded labels)
LOAD * from a.txt (unicode, txt, delimiter is ',' , embedded labels)
LOAD * from a.txt (codepage is 10000, txt, delimiter is ',' , no labels)
```

Table format

The table format is a file specifier for the **LOAD** statement that defines the file type. If nothing is specified, a *.txt* file is assumed.

Specified file types

File type	Description
txt	In a delimited text file the columns in the table are separated by a delimiter character.
fix	<p>In a fixed record file, each field is exactly a certain number of characters.</p> <p>Typically, many fixed record length files contains records separated by a linefeed, but there are more advanced options to specify record size in bytes or to span over more than one line with Record is.</p> <div style="border: 1px solid gray; padding: 5px; margin-top: 10px;">  <i>If the data contains multi-byte characters, field breaks can become misaligned as the format is based on a fixed length in bytes.</i> </div>
dif	In a <i>.dif</i> file, (Data Interchange Format) a special format for defining the table is used.

File type	Description
biff	QlikView can also interpret data in standard Excel files by means of the <i>biff</i> format (Binary Interchange File Format).
ooxml	Excel 2007 and later versions use the ooxml <i>.xlsx</i> format.
html	If the table is part of an html page or file, html should be used.
xml	xml (Extensible Markup Language) is a common markup language that is used to represent data structures in a textual format.
qvd	The format <i>qvd</i> is the proprietary QVD files format, exported from a QlikView document.
qvx	<i>qvx</i> is a file/stream format for high performance output to QlikView.

Delimiter

For delimited table files, an arbitrary delimiter can be specified through the **delimiter is** specifier. This specifier is relevant only for delimited *.txt* files.

Syntax:

```
delimiter is char
```

Arguments:

Delimiter is arguments

Argument	Description
char	Specifies a single character from the 127 ASCII characters.
'\t'	representing a tab sign, with or without quotation marks.
'\\'	representing a backslash (\) character.
'spaces'	representing all combinations of one or more spaces. Non-printable characters with an ASCII-value below 32, with the exception of CR and LF, will be interpreted as spaces.

If nothing is specified, **delimiter is ','** is assumed.

Example:

```
LOAD * from a.txt (utf8, txt, delimiter is ',' , embedded labels);
```

No eof

The **no eof** specifier is used to disregard end-of-file character when loading delimited *.txt* files.

Syntax:

```
no eof
```

If the **no eof** specifier is used, characters with code point 26, which otherwise denotes end-of-file, are disregarded and can be part of a field value.

It is relevant only for delimited text files.

Example:

```
LOAD * from a.txt (txt, utf8, embedded labels, delimiter is ' ', no eof);
```

Labels

Labels is a file specifier for the **LOAD** statement that defines where in a file the field names can be found.

Syntax:

```
embedded labels|explicit labels|no labels
```

The field names can be found in different places of the file. If the first record contains the field names, **embedded labels** should be used. If there are no field names to be found, **no labels** should be used. In *dif* files, a separate header section with explicit field names is sometimes used. In such a case, **explicit labels** should be used. If nothing is specified, **embedded labels** is assumed, also for *dif* files.

Example 1:

```
LOAD * from a.txt (unicode, txt, delimiter is ',', embedded labels
```

Example 2:

```
LOAD * from a.txt (codePage is 1252, txt, delimiter is ',', no labels)
```

Header is

Specifies the header size in table files. An arbitrary header length can be specified through the **header is** specifier. A header is a text section not used by QlikView.

Syntax:

```
header is n  
header is line  
header is n lines
```

The header length can be given in bytes (**header is n**), or in lines (**header is line** or **header is n lines**). **n** must be a positive integer, representing the header length. If not specified, **header is 0** is assumed. The **header is** specifier is only relevant for table files.

Example:

This is an example of a data source table containing a header text line that should not be interpreted as data by QlikView.

```
*Header line  
col1,col2  
a,B  
c,D
```

Using the **header is 1 lines** specifier, the first line will not be loaded as data. In the example, the **embedded labels** specifier tells QlikView to interpret the first non-excluded line as containing field labels.

```
LOAD Col1, Col2
FROM header.txt
(txt, embedded labels, delimiter is ',', msq, header is 1 lines);
```

The result is a table with two fields, Col1 and Col2.

Record is

For fixed record length files, the record length must be specified through the **record is** specifier.

Syntax:

```
Record is n
Record is line
Record is n lines
```

Arguments:

Record is arguments

Argument	Description
n	Specifies the record length in bytes.
line	Specifies the record length as one line.
n lines	Specifies the record length in lines where n is a positive integer representing the record length.

Limitations:

The **record is** specifier is only relevant for **fix** files.

Quotes

Quotes is a file specifier for the **LOAD** statement that defines whether quotes can be used and the precedence between quotes and separators. For text files only.

Syntax:

```
no quotes
msq
```

If the specifier is omitted, standard quoting is used, that is, the quotes "" or '' can be used, but only if they are the first and last non blank character of a field value.

Arguments:

Quotes arguments

Argument	Description
no quotes	Used if quotation marks are not to be accepted in a text file.

Argument	Description
msq	Used to specify modern style quoting, allowing multi-line content in fields. Fields containing end-of-line characters must be enclosed within double quotes. One limitation of the msq option is that single double-quote (") characters appearing as first or last character in field content will be interpreted as start or end of multi-line content, which may lead to unpredicted results in the data set loaded. In this case you should use standard quoting instead, omitting the specifier.

XML

This script specifier is used when loading xml files. Valid options for the **XML** specifier are listed in syntax.

You cannot load DTD files in QlikView.

Syntax:

```
xmlsimple
```

Let

The **let** statement is a complement to the **set** statement, used for defining script variables. The **let** statement, in opposition to the **set** statement, evaluates the expression on the right side of the '=' before it is assigned to the variable.

Syntax:

```
Let variablename=expression
```

The word **let** may be omitted, but the statement then becomes a control statement. Such a statement without the keyword **let** must be contained within a single script row and may be terminated either with a semicolon or end-of-line.

Examples and results:

Examples and results

Example	Result
Set x=3+4; Let y=3+4; z=\$(y)+1;	\$(x) will be evaluated as '3+4' \$(y) will be evaluated as '7' \$(z) will be evaluated as '8'
Let T=now();	\$(T) will be given the value of the current time.

Loosen Table

One or more QlikView internal data tables can be explicitly declared loosely coupled during script execution by using a **Loosen Table** statement. When a table is loosely coupled, all associations between field values in the table are removed. A similar effect could be achieved by loading each field of the loosely coupled table as independent, unconnected tables. Loosely coupled tables can be useful during testing to temporarily isolate different parts of the data structure. A loosely coupled table can be identified in the table viewer by the dotted line and arrow. The use of one or more **Loosen Table** statements in the script will make QlikView disregard any setting of tables as loosely coupled made before the script execution.

Syntax:

```
Loosen Tabletablename [ , tablename2 ...]  
Loosen Tablestablename [ , tablename2 ...]
```

Either syntax: **Loosen Table** or **Loosen Tables** can be used.

*Should QlikView find circular references in the data structure which cannot be broken by tables declared loosely coupled interactively or explicitly in the script, one or more additional tables will be forced loosely coupled until no circular references remain. When this happens, the **Loop Warning** dialog, gives a warning.*

Example:

```
Tab1:  
SELECT * from Trans;  
Loosen Table Tab1;
```

Map

The **map ... using** statement is used for mapping a certain field value or expression to the values of a specific mapping table. The mapping table is created through the **Mapping** statement.

Syntax:

```
Map *fieldlist Using mapname
```

The automatic mapping is done for fields loaded after the **Map ... Using** statement until the end of the script or until an **Unmap** statement is encountered.

The mapping is done last in the chain of events leading up to the field being stored in the internal table in QlikView. This means that mapping is not done every time a field name is encountered as part of an expression, but rather when the value is stored under the field name in the internal table. If mapping on the expression level is required, the **Applymap()** function has to be used instead.

Arguments:

Map arguments

Argument	Description
<i>*fieldlist</i>	A comma separated list of the fields that should be mapped from this point in the script. Using * as field list indicates all fields. The wildcard characters * and ? are allowed in field names. Quoting of field names may be necessary when wildcards are used.
<i>mapname</i>	The name of a mapping table previously read in a mapping load or mapping select statement.

Examples and results:

Examples and results

Example	Result
Map Country Using Cmap;	Enables mapping of the field Country using the map Cmap.
Map A, B, C Using X;	Enables mapping of the fields A, B and C using the map X.
Map * Using GenMap;	Enables mapping of all fields using GenMap.

NullAsNull

The **NullAsNull** statement turns off the conversion of NULL values to string values previously set by a **NullAsValue** statement.

Syntax:

```
NullAsNull *fieldlist
```

The **NullAsValue** statement operates as a switch and can be turned on or off several times in the script, using either a **NullAsValue** or a **NullAsNull** statement.

Arguments:

NullAsNull arguments

Argument	Description
<i>*fieldlist</i>	A comma separated list of the fields for which NullAsNull should be turned on. Using * as field list indicates all fields. The wildcard characters * and ? are allowed in field names. Quoting of field names may be necessary when wildcards are used.

Example:

```
NullAsNull A,B;
LOAD A,B from x.csv;
```

NullAsValue

The **NullAsValue** statement specifies for which fields that NULL should be converted to a value.

Syntax:

```
NullAsValue *fieldlist
```

By default, QlikView considers NULL values to be missing or undefined entities. However, certain database contexts imply that NULL values are to be considered as special values rather than simply missing values. The fact that NULL values are normally not allowed to link to other NULL values can be suspended by means of the **NullAsValue** statement.

The **NullAsValue** statement operates as a switch and will operate on subsequent loading statements. It can be switched off again by means of the **NullAsNull** statement.

Arguments:

NullAsValue arguments

Argument	Description
*fieldlist	A comma separated list of the fields for which NullAsValue should be turned on. Using * as field list indicates all fields. The wildcard characters * and ? are allowed in field names. Quoting of field names may be necessary when wildcards are used.

Example:

```
NullAsValue A,B;  
Set NullValue = 'NULL';  
LOAD A,B from x.csv;
```

Only

The **Only** script keyword is used as an aggregation function, or as part of the syntax in partial reload prefixes **Add**, **Replace**, and **Merge**.

Qualify

The **Qualify** statement is used for switching on the qualification of field names, i.e. field names will get the table name as a prefix.

Syntax:

```
Qualify *fieldlist
```

The automatic join between fields with the same name in different tables can be suspended by means of the **qualify** statement, which qualifies the field name with its table name. If qualified, the field name(s) will be renamed when found in a table. The new name will be in the form of *tablename.fieldname*. *Tablename* is equivalent to the label of the current table, or, if no label exists, to the name appearing after **from** in **LOAD** and **SELECT** statements.

The qualification will be made for all fields loaded after the **qualify** statement.

Qualification is always turned off by default at the beginning of script execution. Qualification of a field name can be activated at any time using a **qualify** statement. Qualification can be turned off at any time using an **Unqualify** statement.

*The **qualify** statement should not be used in conjunction with partial reload.*

Arguments:

Qualify arguments

Argument	Description
*fieldlist	A comma separated list of the fields for which qualification should be turned on. Using * as field list indicates all fields. The wildcard characters * and ? are allowed in field names. Quoting of field names may be necessary when wildcards are used.

Example 1:

```
Qualify B;  
LOAD A,B from x.csv;  
LOAD A,B from y.csv;
```

The two tables **x.csv** and **y.csv** are associated only through **A**. Three fields will result: A, x.B, y.B.

Example 2:

In an unfamiliar database, it is often useful to start out by making sure that only one or a few fields are associated, as illustrated in this example:

```
qualify *;  
unqualify TransID;  
SQL SELECT * from tab1;  
SQL SELECT * from tab2;  
SQL SELECT * from tab3;
```

Only **TransID** will be used for associations between the tables *tab1*, *tab2* and *tab3*.

Rem

The **rem** statement is used for inserting remarks, or comments, into the script, or to temporarily deactivate script statements without removing them.

Syntax:

```
Rem string
```

Everything between the **rem** and the next semicolon ; is considered to be a comment.

There are two alternative methods available for making comments in the script:

1. It is possible to create a comment anywhere in the script - except between two quotes - by placing the section in question between `/*` and `*/`.
2. When typing `//` in the script, all text that follows to the right on the same row becomes a comment. (Note the exception `//:` that may be used as part of an Internet address.)

Arguments:

Rem arguments

Argument	Description
string	An arbitrary text.

Example:

```
Rem ** This is a comment **;  
/* This is also a comment */  
// This is a comment as well
```

Rename field

This script function renames one or more existing QlikView field(s) after they have been loaded.

It is not recommended to use the same name for a field and a variable in QlikView.

Either syntax: **rename field** or **rename fields** can be used.

Syntax:

```
Rename Field (using mapname | oldname to newname{ , oldname to newname })  
Rename Fields (using mapname | oldname to newname{ , oldname to newname })
```

Arguments:

Rename field arguments

Argument	Description
mapname	The name of a previously loaded mapping table containing one or more pairs of old and new field names.
oldname	The old field name.
newname	The new field name.

Limitations:

Two differently named fields cannot be renamed to having the same name. The script will run without errors, but the second field will not be renamed.

Example 1:

```
Rename Field XAZ0007 to Sales;
```

Example 2:

```
FieldMap:  
Mapping SQL SELECT oldnames, newnames from datadictionary;  
Rename Fields using FieldMap;
```

Rename table

This script function renames one or more existing QlikView internal table(s) after they have been loaded.

Either syntax: **rename table** or **rename tables** can be used.

Syntax:

```
Rename Table (using mapname | oldname to newname{ , oldname to newname })  
Rename Tables (using mapname | oldname to newname{ , oldname to newname })
```

Arguments:

Rename table arguments

Argument	Description
mapname	The name of a previously loaded mapping table containing one or more pairs of old and new table names.
oldname	The old table name.
newname	The new table name.

Limitations:

Two differently named tables cannot be renamed to having the same name. The script will run without errors, but the second table will not be renamed.

Example 1:

```
Tab1:  
SELECT * from Trans;  
Rename Table Tab1 to Xyz;
```

Example 2:

```
TabMap:  
Mapping LOAD oldnames, newnames from tabnames.csv;  
Rename Tables using TabMap;
```

Section

With the **section** statement, it is possible to define whether the subsequent **LOAD** and **SELECT** statements should be considered as data or as a definition of the access rights.

Syntax:

```
Section (access | application)
```

If nothing is specified, **section application** is assumed. The **section** definition is valid until a new **section** statement is made.

Example:

```
Section access;  
Section application;
```

Select

The selection of fields from an ODBC data source or OLE DB provider is made through standard SQL **SELECT** statements. However, whether the **SELECT** statements are accepted depends on the ODBC driver or OLE DB provider used.

Syntax:

```
Select [all | distinct | distinctrow | top n [percent] ] fieldlist  
  
From tablelist  
  
[where criterion ]  
  
[group by fieldlist [having criterion ] ]  
  
[order by fieldlist [asc | desc] ]  
  
[ (Inner | Left | Right | Full) join tablename on fieldref = fieldref ]
```

Furthermore, several **SELECT** statements can sometimes be concatenated into one through the use of a **union** operator:

```
selectstatement Union selectstatement
```

The **SELECT** statement is interpreted by the ODBC driver or OLE DB provider, so deviations from the general SQL syntax might occur depending on the capabilities of the ODBC drivers or OLE DB provider, for example:

- **as** is sometimes not allowed, i.e. *aliasname* must follow immediately after *fieldname*.
- **as** is sometimes compulsory if an *aliasname* is used.
- **distinct**, **as**, **where**, **group by**, **order by**, or **union** is sometimes not supported.
- The ODBC driver sometimes does not accept all the different quotation marks listed above.

*This is not a complete description of the SQL **SELECT** statement! E.g. **SELECT** statements can be nested, several joins can be made in one **SELECT** statement, the number of functions allowed in expressions is sometimes very large, etc.*

Arguments:

Select arguments

Argument	Description
distinct	distinct is a predicate used if duplicate combinations of values in the selected fields only should be loaded once.
distinctrow	distinctrow is a predicate used if duplicate records in the source table only should be loaded once.
fieldlist	<p>fieldlist ::= (* field) {, field } A list of the fields to be selected. Using * as field list indicates all fields in the table.</p> <p>fieldlist ::= field {, field } A list of one or more fields, separated by commas.</p> <p>field ::= (fieldref expression) [as aliasname] The expression can e.g. be a numeric or string function based on one or several other fields. Some of the operators and functions usually accepted are: +, -, *, /, & (string concatenation), sum(fieldname), count(fieldname), avg(fieldname)(average), month(fieldname), etc. See the documentation of the ODBC driver for more information.</p> <p>fieldref ::= [tablename.] fieldname The tablename and the fieldname are text strings identical to what they imply. They must be enclosed by straight double quotation marks if they contain e.g. spaces. The as clause is used for assigning a new name to the field.</p>
from	<p>tablelist ::= table {, table } The list of tables that the fields are to be selected from.</p> <p>table ::= tablename [[as] aliasname] The tablename may or may not be put within quotes.</p>
where	<p>where is a clause used for stating whether a record should be included in the selection or not.</p> <p>criterion is a logical expression that can sometimes be very complex. Some of the operators accepted are: numeric operators and functions, =, <> or #(not equal), >, >=, <, <=, and, or, not, exists, some, all, in and also new SELECT statements. See the documentation of the ODBC driver or OLE DB provider for more information.</p>
group by	group by is a clause used for aggregating (group) several records into one. Within one group, for a certain field, all the records must either have the same value, or the field can only be used from within an expression, e.g. as a sum or an average. The expression based on one or several fields is defined in the expression of the field symbol.
having	having is a clause used for qualifying groups in a similar manner to how the where clause is used for qualifying records.
order by	order by is a clause used for stating the sort order of the resulting table of the SELECT statement.

Argument	Description
join	join is a qualifier stating if several tables are to be joined together into one. Field names and table names must be put within quotes if they contain blank spaces or letters from the national character sets. When the script is automatically generated by QlikView, the quotation mark used is the one preferred by the ODBC driver or OLE DB provider specified in the data source definition of the data source in the Connect statement.

Example 1:

```
SELECT * FROM `Categories`;
```

Example 2:

```
SELECT `Category ID`, `Category Name` FROM `Categories`;
```

Example 3:

```
SELECT `Order ID`, `Product ID`,  
`Unit Price` * Quantity * (1-Discount) as NetSales  
FROM `Order Details`;
```

Example 4:

```
SELECT `Order Details`.`Order ID`,  
Sum(`Order Details`.`Unit Price` * `Order Details`.Quantity) as `Result`  
FROM `Order Details`, Orders  
where Orders.`Order ID` = `Order Details`.`Order ID`  
group by `Order Details`.`Order ID`;
```

Set

The **set** statement is used for defining script variables. These can be used for substituting strings, paths, drives, and so on.

Syntax:

```
Set variablename=string
```

Example 1:

```
set FileToUse=Data1.csv;
```

Example 2:

```
set Constant="My string";
```

Example 3:

```
set BudgetYear=2012;
```

Sleep

The **sleep** statement pauses script execution for a specified time.

Syntax:

```
Sleep n
```

Arguments:

Sleep arguments

Argument	Description
n	Stated in milliseconds, where <i>n</i> is a positive integer no larger than 3600000 (i.e. 1 hour). The value may be an expression.

Example 1:

```
Sleep 10000;
```

Example 2:

```
Sleep t*1000;
```

SQL

The **SQL** statement allows you to send an arbitrary SQL command through an ODBC or OLE DB connection.

Syntax:

```
SQL sql_command
```

Sending SQL statements which update the database will return an error if QlikView has opened the ODBC connection in read-only mode.

The syntax:

```
SQL SELECT * from tab1;
```

is allowed, and is the preferred syntax for **SELECT**, for reasons of consistency. The SQL prefix will, however, remain optional for **SELECT** statements.

Arguments:

SQL arguments

Argument	Description
<i>sql_command</i>	A valid SQL command.

Example 1:

```
SQL leave;
```

Example 2:

```
SQL Execute <storedProc>;
```

SQLColumns

The **sqlcolumns** statement returns a set of fields describing the columns of an ODBC or OLE DB data source, to which a **connect** has been made.

Syntax:

```
SQLcolumns
```

The fields can be combined with the fields generated by the **sqltables** and **sqltypes** commands in order to give a good overview of a given database. The twelve standard fields are:

TABLE_QUALIFIER

TABLE_OWNER

TABLE_NAME

COLUMN_NAME

DATA_TYPE

TYPE_NAME

PRECISION

LENGTH

SCALE

RADIX

NULLABLE

REMARKS

For a detailed description of these fields, see an ODBC reference handbook.

Example:

```
Connect to 'MS Access 7.0 Database; DBQ=C:\Course3\DataSrc\QWT.mbd';  
SQLcolumns;
```

Some ODBC drivers may not support this command. Some ODBC drivers may produce additional fields.

SQLTables

The **sqltables** statement returns a set of fields describing the tables of an ODBC or OLE DB data source, to which a **connect** has been made.

Syntax:

```
SQLTables
```

The fields can be combined with the fields generated by the **sqlcolumns** and **sqltypes** commands in order to give a good overview of a given database. The five standard fields are:

TABLE_QUALIFIER

TABLE_OWNER

TABLE_NAME

TABLE_TYPE

REMARKS

For a detailed description of these fields, see an ODBC reference handbook.

Example:

```
Connect to 'MS Access 7.0 Database; DBQ=C:\Course3\DataSrc\QWT.mbd';  
SQLTables;
```

Some ODBC drivers may not support this command. Some ODBC drivers may produce additional fields.

SQLTypes

The **sqltypes** statement returns a set of fields describing the types of an ODBC or OLE DB data source, to which a **connect** has been made.

Syntax:

```
SQLTypes
```

The fields can be combined with the fields generated by the **sqlcolumns** and **sqltables** commands in order to give a good overview of a given database. The fifteen standard fields are:

TYPE_NAME

DATA_TYPE

PRECISION

LITERAL_PREFIX

LITERAL_SUFFIX

CREATE_PARAMS
NULLABLE
CASE_SENSITIVE
SEARCHABLE
UNSIGNED_ATTRIBUTE
MONEY
AUTO_INCREMENT
LOCAL_TYPE_NAME
MINIMUM_SCALE
MAXIMUM_SCALE

For a detailed description of these fields, see an ODBC reference handbook.

Example:

```
Connect to 'MS Access 7.0 Database; DBQ=C:\Course3\DataSrc\QWT.mbd';  
SQLTypes;
```

Some ODBC drivers may not support this command. Some ODBC drivers may produce additional fields.

Star

The string used for representing the set of all the values of a field in the database can be set through the **star** statement. It affects the subsequent **LOAD** and **SELECT** statements.

Syntax:

```
Star is [ string ]
```

Arguments:

Star is arguments

Argument	Description
string	An arbitrary text. Note that the string must be enclosed by quotation marks if it contains blanks. If nothing is specified, star is; is assumed, i.e. there is no star symbol available unless explicitly specified. This definition is valid until a new star statement is made.

The **Star is** statement is not recommended for use in the data part of the script (under **Section Application**) if section access is used. The star character is however fully supported for the protected fields in the **Section Access** part of the script. In this case you do not need to use the explicit **Star is** statement since this is always implicit in section access.

Limitations

- You cannot use the star character with key fields; that is, fields that link tables.
- You cannot use the star character with any fields affected by the **Unqualify** statement as this can affect fields that link tables.
- You cannot use the star character with non-logical tables, for example, info-load tables or mapping-load tables.
- When the star character is used in a reducing field (a field that links to the data) in section access, it represents the values listed in this field in section access. It does not represent other values that may exist in the data but are not listed in section access.
- You cannot use the star character with fields affected by any form of data reduction outside the **Section Access** area.

Example:

The example below is an extract of a data load script featuring section access.

```
star is *;

Section Access;
LOAD * INLINE [
ACCESS, USERID, PASSWORD, OMIT
ADMIN, ADMIN, ADMIN,
USER, USER1, U1, SALES
USER, USER2, U2, WAREHOUSE
USER, USER3, U3, EMPLOYEES
USER, USER4, U4, SALES
USER, USER4, U4, WAREHOUSE
USER, USER5, U5, *
];

Section Application;
LOAD * INLINE [
SALES, WAREHOUSE, EMPLOYEES, ORDERS
1, 2, 3, 4
];
```

The following applies:

- The *Star* sign is *.
- The user *USER1* is not able to see the field *SALES*.
- The user *USER2* is not able to see the field *WAREHOUSE*.
- The user *USER3* cannot see the field *EMPLOYEES*.
- The user *USER4* is added twice to the solution to OMIT two fields for this user, *SALES* and *WAREHOUSE*.

- The *USER5* has a “*” added which means that all listed fields in OMIT are unavailable. The star sign * means all listed values, not all values of the field.
- The user *USER5* cannot see the fields *SALES*, *WAREHOUSE* and *EMPLOYEES* but this user can see the field *ORDERS*.

Store

This script function creates a QVD or a CSV file.

Syntax:

```
Store [ *fieldlist from] table into filename [ format-spec ];
```

The statement will create an explicitly named QVD or CSV file. The statement can only export fields from one data table. If fields from several tables are to be exported, an explicit join must be made previously in the script to create the data table that should be exported.

The text values are exported to the CSV file in UTF-8 with BOM format. A delimiter can be specified, see **LOAD**. The **store** statement to a CSV file does not support BIFF export.

Arguments:

Store arguments	
Argument	Description
<i>*fieldlist</i> ::= (* <i>field</i>) { , <i>field</i> }	<p>A list of the fields to be selected. Using * as field list indicates all fields.</p> <p><i>field</i>::= <i>fieldname</i> [as<i>aliasname</i>]</p> <p><i>fieldname</i> is a text that is identical to a field name in <i>table</i>. (Note that the field name must be enclosed b straight double quotation marks or square brackets if it contains spaces or other non-standard characters.)</p> <p><i>aliasname</i> is an alternate name for the field to be used in the resulting QVD or CSV file.</p>
<i>table</i>	A script label representing an already loaded table to be used as source for data.

Argument	Description
<i>filename</i>	<p>The name of the target file including a valid path.</p> <ul style="list-style-type: none"> absolute <p>Example: <i>c:\datasales.qvd</i></p> <ul style="list-style-type: none"> relative to the QlikView document path. <p>Example: <i>datasales.qvd</i></p> <p>If the path is omitted, QlikView stores the file in the directory specified by the Directory statement. If there is no Directory statement, QlikView stores the file in the working directory.</p>
<i>format-spec ::= (txt qvd)</i>	<p>The format specification consists of the text txt for text files, or the text qvd for qvd files. If the format specification is omitted, qvd is assumed.</p>

Examples:

```

Store mytable into xyz.qvd (qvd);
Store * from mytable into xyz.qvd;
Store Name, RegNo from mytable into xyz.qvd;
Store Name as a, RegNo as b from mytable into xyz.qvd;
store mytable into myfile.txt (txt);
store * from mytable into myfile.txt (txt);

```

Tag

This script statement provides a way to assign tags to one or more fields or tables. If an attempt to tag a field or table not present in the app is made, the tagging will be ignored. If conflicting occurrences of a field or tag name are found, the last value is used.

Syntax:

```
Tag[field|fields] fieldlistwith tagname
```

```
Tag[field|fields] fieldlistusing mapname
```

```
Tagtabletablelistwith tagname
```

Arguments:

Tag arguments

Argument	Description
<i>fieldlist</i>	One or several fields that should be tagged, in a comma separated list.

Argument	Description
mapname	The name of a mapping table previously loaded in a mapping Load or mapping Select statement.
tablelist	A comma separated list of the tables that should be tagged.
tagname	The name of the tag that should be applied to the field.

Example 1:

```
tagmap:
mapping LOAD * inline [
a,b
Alpha,MyTag
Num,MyTag
];
tag fields using tagmap;
```

Example 2:

```
tag field Alpha with 'MyTag2';
```

Trace

The **trace** statement writes a string to the **Script Execution Progress** window and to the script log file, when used. It is very useful for debugging purposes. Using **\$**-expansions of variables that are calculated prior to the **trace** statement, you can customize the message.

Syntax:

```
Trace string
```

Example 1:

```
Trace Main table loaded;
```

Example 2:

```
Let MyMessage = NoOfRows('MainTable') & ' rows in Main Table';
Trace $(MyMessage);
```

Unmap

The **Unmap** statement disables field value mapping specified by a previous **Map ... Using** statement for subsequently loaded fields.

Syntax:

```
Unmap *fieldlist
```

Arguments:

Unmap arguments

Argument	Description
*fieldlist	a comma separated list of the fields that should no longer be mapped from this point in the script. Using * as field list indicates all fields. The wildcard characters * and ? are allowed in field names. Quoting of field names may be necessary when wildcards are used.

Examples and results:

Examples and results

Example	Result
Unmap Country;	Disables mapping of field Country.
Unmap A, B, C;	Disables mapping of fields A, B and C.
Unmap * ;	Disables mapping of all fields.

Unqualify

The **Unqualify** statement is used for switching off the qualification of field names that has been previously switched on by the **Qualify** statement.

Syntax:

```
Unqualify *fieldlist
```

Arguments:

Unqualify arguments

Argument	Description
*fieldlist	A comma separated list of the fields for which qualification should be turned on. Using * as field list indicates all fields. The wildcard characters * and ? are allowed in field names. Quoting of field names may be necessary when wildcards are used. Refer to the documentation for the Qualify statement for further information.

Example 1:

In an unfamiliar database, it is often useful to start out by making sure that only one or a few fields are associated, as illustrated in this example:

```
qualify *;  
unqualify TransID;  
SQL SELECT * from tab1;  
SQL SELECT * from tab2;  
SQL SELECT * from tab3;
```

First, qualification is turned on for all fields.

Then qualification is turned off for **TransID**.

Only **TransID** will be used for associations between the tables *tab1*, *tab2* and *tab3*. All other fields will be qualified with the table name.

Untag

This script statement provides a way to remove tags from fields or tables. If an attempt to untag a field or table not present in the app is made, the untagging will be ignored.

Syntax:

```
Untag[field|fields] fieldlistwithtagname
```

```
Untag[field|fields] fieldlistusingmapname
```

```
Untagtabletablelistwithtagname
```

Arguments:

Untag arguments

Argument	Description
fieldlist	One or several fields which tags should be removed, in a comma separated list.
mapname	The name of a mapping table previously loaded in a mapping LOAD or mapping SELECT statement.
tablelist	A comma separated list of the tables that should be untagged.
tagname	The name of the tag that should be removed from the field.

Example 1:

```
tagmap:  
mapping LOAD * inline [  
a,b  
Alpha,MyTag  
Num,MyTag  
];  
Untag fields using tagmap;
```

Example 2:

```
Untag field Alpha with MyTag2;
```

Script variables

A variable in QlikView is a container storing a static value or a calculation, for example a numeric or alphanumeric value. When you use the variable in the document, any change made to the variable is applied everywhere the variable is used. Variables are defined in the script using the script editor, where the variable acquires its value from a **Let**, **Set** or other control statements in the load script.

9 Script syntax and chart functions

If the first character of a variable value is an equals sign '=' QlikView will try to evaluate the value as a formula (QlikView expression) and then display or return the result rather than the actual formula text.

When used, the variable is substituted by its value. Variables can be used in the script for dollar sign expansion and in various control statements. This is very useful if the same string is repeated many times in the script, for example, a path.

Some special system variables will be set by QlikView at the start of the script execution regardless of their previous values.

When defining a variable, the syntax:

```
set variablename = string
```

or

```
let variable = expression
```

is used. The **Set** command assigns the text to the right of the equal sign to the variable, whereas the **Let** command evaluates the expression.

Variables are case sensitive.

Examples:

```
set HidePrefix = $ ; // the variable will get the character '$' as value.
```

```
let vToday = Num(Today()); // returns the date serial number of today.
```

Variable calculation

There are several ways to use variables with calculated values in QlikView, and the result depends on how you define it and how you call it in an expression.

In this example we load some inline data:

```
LOAD * INLINE [  
    Dim, Sales  
    A, 150  
    A, 200  
    B, 240  
    B, 230  
    C, 410  
    C, 330  
];
```

Let's define two variables:

```
Let vSales = 'Sum(Sales)' ;  
Let vSales2 = '=Sum(Sales)' ;
```

In the second variable, we add an equal sign before the expression. This will cause the variable to be calculated before it is expanded and the expression is evaluated.

If you use the vSales variable as it is, for example in a measure, the result will be the string Sum(Sales), that is, no calculation is performed.

If you add a dollar-sign expansion and call `$(vSales)` in the expression, the variable is expanded, and the sum of Sales is displayed.

Finally, if you call `$(vSales2)`, the variable will be calculated before it is expanded. This means that the result displayed is the total sum of Sales. The difference between using `=$(vSales)` and `=$(vSales2)` as measure expressions is seen in this chart showing the results:

Example results

Dim	\$(vSales)	\$(vSales2)
A	350	1560
B	470	1560
C	740	1560

As you can see, `$(vSales)` results in the partial sum for a dimension value, while `$(vSales2)` results in the total sum.

Error variables

The values of all error variables will exist after the script execution. The first variable, `ErrorMode`, is input from the user, and the last three are output from QlikView with information on errors in the script.

Error variables overview

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

ErrorMode

This error variable determines what action is to be taken by QlikView when an error is encountered during script execution.

ErrorMode

ScriptError

This error variable returns the error code of the last executed script statement.

ScriptError

ScriptErrorCount

This error variable returns the total number of statements that have caused errors during the current script execution. This variable is always reset to 0 at the start of script execution.

ScriptErrorCount

ScriptErrorList

This error variable will contain a concatenated list of all script errors that have occurred during the last script execution. Each error is separated by a line feed.

ScriptErrorList

ErrorMode

This error variable determines what action is to be taken by QlikView when an error is encountered during script execution.

Syntax:

```
ErrorMode
```

Arguments:

ErrorMode arguments

Argument	Description
ErrorMode=1	The default setting. The script execution will halt and the user will be prompted for action (non-batch mode).
ErrorMode =0	QlikView will simply ignore the failure and continue script execution at the next script statement.
ErrorMode =2	QlikView will trigger an "Execution of script failed..." error message immediately on failure, without prompting the user for action beforehand.

Example:

```
set ErrorMode=0;
```

ScriptError

This error variable returns the error code of the last executed script statement.

Syntax:

```
ScriptError
```

This variable will be reset to 0 after each successfully executed script statement. If an error occurs it will be set to an internal QlikView error code. Error codes are dual values with a numeric and a text component. The following error codes exist:

ScriptError codes

Error code	Description
0	No error
1	General error
2	Syntax error
3	General ODBC error
4	General OLE DB error
5	General custom database error

Error code	Description
6	General XML error
7	General HTML error
8	File not found
9	Database not found
10	Table not found
11	Field not found
12	File has wrong format
13	BIFF error
14	BIFF error encrypted
15	BIFF error unsupported version
16	Semantic error

Example:

```
set ErrorMode=0;
LOAD * from abc.qvw;
if ScriptError=8 then
exit script;
//no file;
end if
```

ScriptErrorCount

This error variable returns the total number of statements that have caused errors during the current script execution. This variable is always reset to 0 at the start of script execution.

Syntax:

```
ScriptErrorCount
```

ScriptErrorList

This error variable will contain a concatenated list of all script errors that have occurred during the last script execution. Each error is separated by a line feed.

Syntax:

```
ScriptErrorList
```

Number interpretation variables

Number interpretation variables are system defined, that is, they are automatically generated according to the current regional settings of the operating system when a new document is created. In QlikView Desktop, this is according to the settings of the computer operating system, and in QlikView, it is according to the operating system of the server where QlikView is installed.

The variables are included at the top of the script of the new QlikView document and substitute operating system defaults for certain number formatting settings at the time of the script execution. They can be deleted, edited or duplicated freely.

Number interpretation variables overview

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

Currency formatting

MoneyDecimalSep

The decimal separator defined replaces the decimal symbol for currency of the operating system (regional settings).

```
MoneyDecimalSep
```

MoneyFormat

The symbol defined replaces the currency symbol of the operating system (regional settings).

```
MoneyFormat
```

MoneyThousandSep

The thousands separator defined replaces the digit grouping symbol for currency of the operating system (regional settings).

```
MoneyThousandSep
```

Number formatting

DecimalSep

The decimal separator defined replaces the decimal symbol of the operating system (regional settings).

```
DecimalSep
```

ThousandSep

The thousands separator defined replaces the digit grouping symbol of the operating system (regional settings).

```
ThousandSep
```

Time formatting

DateFormat

The format defined replaces the date format of the operating system (regional settings).

```
DateFormat
```

TimeFormat

The format defined replaces the time format of the operating system (regional settings).

```
TimeFormat
```

TimestampFormat

The format defined replaces the date and time formats of the operating system (regional settings).

```
TimestampFormat
```

MonthNames

The format defined replaces the month names convention of the operating system (regional settings).

```
MonthNames
```

LongMonthNames

The format defined replaces the long month names convention of the operating system (regional settings).

```
LongMonthNames
```

DayNames

The format defined replaces the weekday names convention of the operating system (regional settings).

```
DayNames
```

LongDayNames

The format defined replaces the long weekday names convention of the operating system (regional settings).

```
LongDayNames
```

FirstWeekDay

This integer defines which day to use as the first day of the week.

```
FirstWeekDay
```

BrokenWeeks

The setting defines if weeks are broken or not.

```
BrokenWeeks
```

ReferenceDay

The setting defines which day in January to set as reference day to define week 1.

```
ReferenceDay
```

FirstMonthOfYear

The setting defines which month to use as first month of the year, which can be used to define financial years that use a monthly offset, for example starting April 1.

```
FirstMonthOfYear
```

BrokenWeeks

The setting defines if weeks are broken or not.

Syntax:

```
BrokenWeeks
```

By default, QlikView functions use unbroken weeks. This means that:

- In some years, week 1 starts in December, and in other years, week 52 or 53 continues into January.
- Week 1 always has at least 4 days in January.

The alternative is to use broken weeks. This means that:

- Week 52 or 53 do not continue into January.
- Week 1 starts on January 1 and is, in most cases, not a full week.

The following values can be used:

- 0 (=use unbroken weeks)
- 1 (= use broken weeks)

Examples:

```
Set BrokenWeeks=0; //(use unbroken weeks)
Set BrokenWeeks=1; //(use broken weeks)
```

DateFormat

The format defined replaces the date format of the operating system (regional settings).

Syntax:

```
DateFormat
```

Examples:

```
Set DateFormat='M/D/YY'; //(US format)
Set DateFormat='DD/MM/YY'; //(UK date format)
Set DateFormat='YYYY-MM-DD'; //(ISO date format)
```

DayNames

The format defined replaces the weekday names convention of the operating system (regional settings).

Syntax:

```
DayNames
```

Example:

```
Set DayNames='Mon;Tue;Wed;Thu;Fri;Sat;Sun';
```

DecimalSep

The decimal separator defined replaces the decimal symbol of the operating system (regional settings).

Syntax:

```
DecimalSep
```

Examples:

```
Set DecimalSep='.';
Set DecimalSep=',';
```

FirstWeekDay

This integer defines which day to use as the first day of the week.

Syntax:

FirstWeekDay

By default, QlikView functions use Monday as the first day of the week. The following values can be used:

- 0 (= Monday)
- 1 (= Tuesday)
- 2 (= Wednesday)
- 3 (= Thursday)
- 4 (= Friday)
- 5 (= Saturday)
- 6 (= Sunday)

Examples:

```
Set FirstWeekDay=6; //(set Sunday as the first day of the week)
```

LongDayNames

The format defined replaces the long weekday names convention of the operating system (regional settings).

Syntax:

LongDayNames

Example:

```
Set LongDayNames='Monday;Tuesday;Wednesday;Thursday;Friday;Saturday;Sunday';
```

LongMonthNames

The format defined replaces the long month names convention of the operating system (regional settings).

Syntax:

LongMonthNames

Example:

```
Set  
LongMonthNames='January;February;March;April;May;June;July;August;September;October;November;December';
```

MoneyDecimalSep

The decimal separator defined replaces the decimal symbol for currency of the operating system (regional settings).

Syntax:

MoneyDecimalSep

Example:

```
Set MoneyDecimalSep='.';
```

MoneyFormat

The symbol defined replaces the currency symbol of the operating system (regional settings).

Syntax:

```
MoneyFormat
```

Example:

```
Set MoneyFormat='$ #,##0.00; ($ #,##0.00)';
```

MoneyThousandSep

The thousands separator defined replaces the digit grouping symbol for currency of the operating system (regional settings).

Syntax:

```
MoneyThousandSep
```

Example:

```
Set MoneyThousandSep=',';
```

MonthNames

The format defined replaces the month names convention of the operating system (regional settings).

Syntax:

```
MonthNames
```

Example:

```
Set MonthNames='Jan;Feb;Mar;Apr;May;Jun;Jul;Aug;Sep;Oct;Nov;Dec';
```

ReferenceDay

Syntax:

```
ReferenceDay
```

The setting defines which day in January to set as reference day to define week 1. By default, QlikView functions use 4 as the reference day. This means that week 1 must contain January 4, or put differently, that week 1 must always have at least 4 days in January.

The following values can be used to set a different reference day:

- 1 (= January 1)
- 2 (= January 2)
- 3 (= January 3)
- 4 (= January 4)

- 5 (= January 5)
- 6 (= January 6)
- 7 (= January 7)

Examples:

```
Set ReferenceDay=3; //(set January 3 as the reference day)
```

FirstMonthOfYear

The setting defines which month to use as first month of the year, which can be used to define financial years that use a monthly offset, for example starting April 1.

Valid settings are 1 (January) to 12 (December). Default setting is 1.

Syntax:

```
FirstMonthOfYear
```

Example:

```
Set FirstMonthOfYear=4; //Sets the year to start in April
```

ThousandSep

The thousands separator defined replaces the digit grouping symbol of the operating system (regional settings).

Syntax:

```
ThousandSep
```

Examples:

```
Set ThousandSep=','; //(for example, seven billion must be specified as: 7,000,000,000)
Set ThousandSep=' ';
```

TimeFormat

The format defined replaces the time format of the operating system (regional settings).

Syntax:

```
TimeFormat
```

Example:

```
Set TimeFormat='hh:mm:ss';
```

TimestampFormat

The format defined replaces the date and time formats of the operating system (regional settings).

Syntax:

```
TimestampFormat
```

Example:

```
Set TimestampFormat='M/D/YY hh:mm:ss[.fff]';
```

System variables

System variables, some of which are system-defined, provide information about the system and the QlikView document.

System variables overview

Some of the functions are described further after the overview. For those functions, you can click the function name in the syntax to immediately access the details for that specific function.

Include

The **Include/Must_Include** variable specifies a file that contains text that should be included in the script and evaluated as script code. You can store parts of your script code in a separate text file and reuse it in several documents. This is a user-defined variable.

```
$(Include =filename)
$(Must_Include=filename)
```

HidePrefix

All field names beginning with this text string will be hidden in the same manner as the system fields. This is a user-defined variable.

```
HidePrefix
```

HideSuffix

All field names ending with this text string will be hidden in the same manner as the system fields. This is a user-defined variable.

```
HideSuffix
```

StripComments

If this variable is set to 0, stripping of `/*..*/` and `//` comments in the script will be inhibited. If this variable is not defined, stripping of comments will always be performed.

```
StripComments
```

Verbatim

Normally all field values are automatically stripped of leading and trailing blanks (ASCII 32) and tabs (ASCII 9) before being loaded into the QlikView database. Setting this variable to 1 suspends the stripping of blanks and tabs. Hard space (ANSI 160) is never stripped.

```
Verbatim
```

OpenUrlTimeout

This variable defines the timeout in seconds that QlikView should respect when getting data from URL sources (e.g. HTML pages). If omitted, the timeout is about 20 minutes.

OpenUrlTimeout

CollationLocale

Specifies which locale to use for sort order and search matching. The value is the culture name of a locale, for example 'en-US'. This is a system-defined variable.

CollationLocale

HidePrefix

All field names beginning with this text string will be hidden in the same manner as the system fields. This is a user-defined variable.

Syntax:

```
HidePrefix
```

Example:

```
set HidePrefix='_ ' ;
```

If this statement is used, the field names beginning with an underscore will not be shown in the field name lists when the system fields are hidden.

HideSuffix

All field names ending with this text string will be hidden in the same manner as the system fields. This is a user-defined variable.

Syntax:

```
HideSuffix
```

Example:

```
set HideSuffix='% ' ;
```

If this statement is used, the field names ending with a percentage sign will not be shown in the field name lists when the system fields are hidden.

Include

The **Include/Must_Include** variable specifies a file that contains text that should be included in the script and evaluated as script code. You can store parts of your script code in a separate text file and reuse it in several documents. This is a user-defined variable.

Syntax:

```
$(Include=filename)
```

```
$(Must_Include=filename)
```

There are two versions of the variable:

- **Include** does not generate an error if the file cannot be found, it will fail silently.
- **Must_Include** generates an error if the file cannot be found.

If you don't specify a path, the filename will be relative to the QlikView document working directory. You can also specify an absolute file path.

*The construction **set Include =filename** is not applicable.*

Examples:

```
$(Include=abc.txt);  
$(Must_Include=abc.txt);
```

OpenUrlTimeout

This variable defines the timeout in seconds that QlikView should respect when getting data from URL sources (e.g. HTML pages). If omitted, the timeout is about 20 minutes.

Syntax:

```
OpenUrlTimeout
```

Example:

```
set openUrlTimeout=10;
```

StripComments

If this variable is set to 0, stripping of `/*..*/` and `//` comments in the script will be inhibited. If this variable is not defined, stripping of comments will always be performed.

Syntax:

```
StripComments
```

Certain database drivers use `/*..*/` as optimization hints in **SELECT** statements. If this is the case, the comments should not be stripped before sending the **SELECT** statement to the database driver.

It is recommended that this variable be reset to 1 immediately after the statement(s) where it is needed.

Example:

```
set StripComments=0;  
SQL SELECT * /* <optimization directive> */ FROM Table ;  
set StripComments=1;
```

Verbatim

Normally all field values are automatically stripped of leading and trailing blanks (ASCII 32) and tabs (ASCII 9) before being loaded into the QlikView database. Setting this variable to 1 suspends the stripping of blanks and tabs. Hard space (ANSI 160) is never stripped.

Syntax:

```
Verbatim
```

Example:

```
set verbatim = 1;
```

Value handling variables

This section describes variables that are used for handling NULL and other values.

Value handling variables overview

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

NullDisplay

The defined symbol will substitute all NULL values from ODBC, and connectors, on the lowest level of data. This is a user-defined variable.

```
NullDisplay
```

NullInterpret

The defined symbol will be interpreted as NULL when it occurs in a text file, CSV file, or an inline statement. This is a user-defined variable.

```
NullInterpret
```

NullValue

If the **NullAsValue** statement is used, the defined symbol will substitute all NULL values in the **NullAsValue** specified fields with the specified string.

```
NullValue
```

OtherSymbol

Defines a symbol to be treated as 'all other values' before a **LOAD/SELECT** statement. This is a user-defined variable.

```
OtherSymbol
```

NullDisplay

The defined symbol will substitute all NULL values from ODBC, and connectors, on the lowest level of data. This is a user-defined variable.

Syntax:

```
NullDisplay
```

Example:

```
set NullDisplay='<NULL>';
```

NullInterpret

The defined symbol will be interpreted as NULL when it occurs in a text file, CSV file, or an inline statement. This is a user-defined variable.

Syntax:

```
NullInterpret
```

Examples:

```
set NullInterpret=' ' ;
set NullInterpret =;
set NullInterpret ='';
```

NullValue

If the **NullAsValue** statement is used, the defined symbol will substitute all NULL values in the **NullAsValue** specified fields with the specified string.

Syntax:

```
NullValue
```

Example:

```
NullAsValue Field1, Field2;
set NullValue='<NULL>';
```

OtherSymbol

Defines a symbol to be treated as 'all other values' before a **LOAD/SELECT** statement. This is a user-defined variable.

Syntax:

```
OtherSymbol
```

Example:

```
set otherSymbol='+';
LOAD * inline
[X, Y
a, a
b, b];
LOAD * inline
[X, Z
a, a
+, c];
```

The field value Y='b' will now link to Z='c' through the other symbol.

9.4 Script expressions

Expressions can be used in both the **LOAD** statement and the **SELECT** statement. The syntax and functions described here apply to the **LOAD** statement, and not to the **SELECT** statement, since the latter is interpreted by the ODBC driver and not by QlikView. However, most ODBC drivers are often capable of interpreting a number of the functions described below.

Expressions consist of functions, fields and operators, combined in a syntax.

All expressions in a QlikView script return a number and/or a string, whichever is appropriate. Logical functions and operators return 0 for False and -1 for True. Number to string conversions and vice versa are implicit. Logical operators and functions interpret 0 as False and all else as True.

The general syntax for an expression is:

```
expression ::= ( constant | fieldref | operator1 expression | expression operator2 expression  
| function | (expression) )
```

where:

constant is a string (a text, a date or a time) enclosed by single straight quotation marks, or a number. Constants are written with no thousands separator and with a decimal point as decimal separator.

fieldref is a field name of the loaded table.

operator1 is a unary operator (working on one expression, the one to the right).

operator2 is a binary operator (working on two expressions, one on each side).

function ::= functionname(parameters)

parameters ::= expression { , expression }

The number and types of parameters is not arbitrary. It depends on the function used.

Expressions and functions can thus be nested freely, and as long as the expression returns an interpretable value, QlikView will not give any error messages.

9.5 Chart expressions

An expression is a combination of functions, fields, and mathematical operators (+ * / =). Expressions are used to process data in the document in order to produce a result that can be seen in a chart. They are not limited to use in measures. You can build charts that are more dynamic and powerful, with expressions for titles, subtitles, footnotes, and even dimensions.

This means, for example, that instead of the title of a chart being static text, it can be made from an expression whose result changes depending on the selections made.

Defining the aggregation scope

There are usually two factors that together determine which records are used to define the value of aggregation in an expression. When working in visualizations these factors are:

- Dimensional value (of the aggregation in a chart expression)
- Selections

Together, these factors define the scope of the aggregation. You may come across situations where you want your calculation to disregard the selection, the dimension, or both. In chart functions, you can achieve this by using the TOTAL qualifier, set analysis or a combination of the two. In summary:

- To disregard or adjust the dimensional grouping: Use the TOTAL qualifier
- To disregard or adjust the selection: Use set analysis

Aggregation: Method and description

Method	Description
TOTAL qualifier	<p>Using the total qualifier inside your aggregation function disregards the dimensional value.</p> <p>The total qualifier may be used inside an aggregation in order to redefine the aggregation scope by disregarding the dimensional values. The aggregation will instead be performed on all possible field values.</p> <p>The TOTAL qualifier may be followed by a list of one or more field names within angle brackets.</p> <p>For example:</p> <pre>sum(TOTAL <Quarter> {<Year={2013}, Quarter={'Q2'}>} Amount)</pre> <p>These field names should be a subset of the chart dimensions. In this case, the calculation is made disregarding all chart dimensions except those listed, that is, one value is returned for each combination of field values in the listed dimension fields. Also, fields that are not currently a dimension in a chart may be included in the list. This may be useful in the case of group dimensions, where the dimension fields are not fixed. Listing all of the dimensions in the group causes the function to give consistent aggregation results when the drill-down level changes.</p> <p>For an example of adding exceptions in angle brackets, see <i>Example: TOTAL qualifier with exception, and set analysis (page 1004)</i>.</p>
Set analysis	<p>Using set analysis inside your aggregation overrides the selection. The aggregation will be performed on all values split across the dimensions.</p>
TOTAL qualifier and set analysis	<p>Using the TOTAL qualifier and set analysis inside your aggregation overrides the selection and disregards all dimensions, except those listed within angle brackets after the TOTAL qualifier.</p>

9 Script syntax and chart functions

Method	Description
ALL qualifier	Using the ALL qualifier inside your aggregation disregards the selection and the dimensions. The equivalent can be achieved with the {1} set analysis statement and the TOTAL qualifier: <code>=sum(All Sales)</code> <code>=sum({1} Total Sales)</code>

Example: TOTAL qualifier

The following example shows how TOTAL can be used to calculate a relative share. Assuming that Q2 has been selected, using TOTAL calculates the sum of all values disregarding the dimensions.

Example: Total qualifier

Year	Quarter	Sum(Amount)	Sum(TOTAL Amount)	Sum(Amount)/Sum(TOTAL Amount)
		3000	3000	100%
2012	Q2	1700	3000	56,7%
2013	Q2	1300	3000	43,3%

Example: Set analysis

The following example shows how set analysis can be used to make a comparison between data sets before any selection was made. Assuming that Q2 has been selected, using set analysis with the set definition {1} calculates the sum of all values disregarding any selections but split by the dimensions.

Example: Set analysis

Year	Quarter	Sum(Amount)	Sum({1} Amount)	Sum(Amount)/Sum({1} Amount)
		3000	10800	27,8%
2012	Q1	0	1100	0%
2012	Q3	0	1400	0%
2012	Q4	0	1800	0%
2012	Q2	1700	1700	100%
2013	Q1	0	1000	0%
2013	Q3	0	1100	0%
2013	Q4	0	1400	0%
2013	Q2	1300	1300	100%

Example: TOTAL qualifier and set analysis ({1} identifier)

The following example shows how set analysis and the TOTAL qualifier can be combined to make a comparison between data sets before any selection was made and across all dimensions. Assuming that Q2 has been selected, using set analysis with the set definition {1} and the TOTAL qualifier calculates the sum of all values disregarding any selections and disregarding the dimensions.

Example: TOTAL qualifier and set analysis

Year	Quarter	Sum (Amount)	Sum({1} TOTAL Amount)	Sum(Amount)/Sum({1} TOTAL Amount)
		3000	10800	27,8%
2012	Q2	1700	10800	15,7%
2013	Q2	1300	10800	12%

Example: TOTAL qualifier and set analysis (comparing data against a reference value)

The following example shows how you can use set analysis and the TOTAL qualifier to create a reference columns in your table for easy row-level comparison of metrics. To make the data easier to understand and consume, we label the measure columns.

The data from the second quarter of 2013 is used as a reference to compare against all other values in the table.

Do the following:

1. Add a table to your sheet.
2. Add the following fields as dimensions:
 - *Year*
 - *Quarter*
3. Add the following measure:
Sum(Amount)
4. In the properties for the measure you just added, give the measure the following label: *Total Sales*
5. Add the following measure:
Sum(TOTAL {<Year={2013}, Quarter={'Q2'}>} Amount)
6. In the properties for the measure you just added, give the measure the following label: *Reference Quarter (2013-Q2) Total Sales*
7. Add the following measure:
round((sum(Amount) / sum(total {<Year={2013}, Quarter={'Q2'}>} Amount))*100, '0.01') & '%'
8. In the properties for the measure you just added, give the measure the following label: *Rounded Quotient - Total Sales Compared to Reference Quarter (2013-Q2)*

With no selections applied, your table should look like the following:

Example: TOTAL qualifier and set analysis (reference column)

Year	Quarter	Total Sales	Reference Quarter (2013-Q2) Total Sales	Rounded Quotient - Total Sales Compared to Reference Quarter (2013-Q2)
2012	Q1	1100	1300	84.62%
2012	Q2	1700	1300	130.77%
2012	Q3	1400	1300	107.69%
2012	Q4	1800	1300	138.46%
2013	Q1	1000	1300	76.92%
2013	Q2	1300	1300	100.00%
2013	Q3	1100	1300	84.62%
2013	Q4	1400	1300	107.69%

Example: TOTAL qualifier with exception, and set analysis

The following example shows how to use the TOTAL qualifier, but with an exception to this qualifier noted in angle brackets. The example expressions also uses set analysis.

Do the following:

1. Add a table to your sheet.
2. Add the following fields as dimensions:
 - *Year*
 - *Quarter*
3. Add the following measure:

Sum(Amount)
4. In the properties for the measure you just added, give the measure the following label: *Total Sales*
5. Add the following measure:

Sum(TOTAL <Quarter> {<Year={2013}, Quarter={'Q2'}>} Amount)
6. In the properties for the measure you just added, give the measure the following label: *Reference Quarter (2013-Q2) Total Sales*

Examples: TOTAL qualifier with exception, and set analysis

Year	Quarter	Total Sales	Reference Quarter (2013-Q2) Total Sales
2012	Q1	1100	0
2012	Q2	1700	1300
2012	Q3	1400	0
2012	Q4	1800	0
2013	Q1	1000	0

Year	Quarter	Total Sales	Reference Quarter (2013-Q2) Total Sales
2013	Q2	1300	1300
2013	Q3	1100	0
2013	Q4	1400	0

The reference column expression is interpreted as follows:

- The set expression {<Year={2013}, Quarter={'Q2'}>} restricts input data to records with a year of 2013 and a quarter of Q2.
- The TOTAL qualifier ensures all dimensions in the table are disregarded. However, with the <Quarter> specifier, an exception is made for the quarter dimension.

Data used in examples on this page

Data used in examples:

AggregationScope:

```
LOAD * inline [  
Year Quarter Amount  
2012 Q1 1100  
2012 Q2 1700  
2012 Q3 1400  
2012 Q4 1800  
2013 Q1 1000  
2013 Q2 1300  
2013 Q3 1100  
2013 Q4 1400] (delimiter is ' ');
```

Special input field aggregation functions

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

The following special aggregation functions can be used for input fields.

inputavg

inputavg() returns the aggregated average of **inputfield** iterated over the chart dimension(s). **inputfield** must be a field name of a field properly declared as an input field in the script.

```
inputavg (page 1006) ([inputfield [, distribution_mode][set_expression])
```

inputsum

inputsum() returns the aggregated sum of **inputfield** iterated over the chart dimension(s). **inputfield** must be a field name of a field properly declared as an input field in the script.

```
inputsum (page 1007) ([inputfield [, distribution_mode][set_expression])
```

inputavg

inputavg() returns the aggregated average of **inputfield** iterated over the chart dimension(s). **inputfield** must be a field name of a field properly declared as an input field in the script.

Syntax:

```
inputavg(inputfield [, distribution_mode] [set_expression])
```

When this aggregation function is used as expression in a table chart, it will be possible to edit the aggregated value interactively. When hovering over the expression cell you will see an input icon. Clicking on the icon sets the cell in input edit mode. It is possible to use up/down arrow keys to move between cells while staying in input edit mode. The change in the aggregated value will be distributed to the underlying field values using the chosen **distribution_mode**. The entire QlikView document will automatically recalculate whenever new values are entered.

The **distribution_mode** parameter can have the following values:

distribution_mode parameter values

Parameter	Description
'+'	Default mode. Equal parts of the change are distributed to all the underlying values.
'*'	The change is distributed proportionally (to existing values) to the underlying values.
'='	The value entered is given to all the underlying values.
'/'	The value is divided equally between underlying values, without regard to previous distribution but keeping previous average.

The **distribution_mode** values in the previous table can be amended with the following modifiers:

distribution_mode parameter value modifiers

Modifier	Description
T	E.g. '+T'. Will cause a compensation of the entered change over the other selected values in the input field (keeping the grand total intact).
A	E.g. '+A'. Will cause a compensation of the entered change over all other values (keeping the grand total intact).

Examples:

```
inputavg (Budget )  
inputavg (Budget, '+' )  
inputavg (Budget, '*' )  
inputavg (Budget, '=' )  
inputavg (Budget, '/' )  
inputavg (Budget, '+T' )  
inputavg (Budget, '+A' )
```

inputsum

inputsum() returns the aggregated sum of **inputfield** iterated over the chart dimension(s). **inputfield** must be a field name of a field properly declared as an input field in the script.

Syntax:

```
inputsum(inputfield [, distribution_mode] [set_expression])
```

When this aggregation function is used as expression in a table chart, it will be possible to edit the aggregated sum interactively. When hovering over the expression cell you will see an input icon. Clicking on the icon sets the cell in input edit mode. It is possible to use up/down arrow keys to move between cells while staying in input edit mode. The change in the aggregated sum will be distributed to the underlying field values using the chosen **distribution_mode**. The entire QlikView document will automatically recalculate whenever new values are entered.

The **distribution_mode** parameter can have the following values:

distribution_mode parameter values

Parameter	Description
'+'	Default mode. Equal parts of the change are distributed to all the underlying values.
'*'	The change is distributed proportionally (to existing values) to the underlying values.
'='	The value entered is given to all the underlying values.
'/'	The value is divided equally between underlying values, without regard to previous distribution but keeping previous sum.

The **distribution_mode** values in the previous table can be amended with the following modifiers:

distribution_mode parameter value modifiers

Modifier	Description
T	E.g. '+T'. Will cause a compensation of the entered change over the other selected values in the input field (keeping the grand total intact).
A	E.g. '+A'. Will cause a compensation of the entered change over all other values (keeping the grand total intact).

Examples:

```
inputsum (Budget )  
inputsum (Budget, '+' )  
inputsum (Budget, '*' )  
inputsum (Budget, '=' )  
inputsum (Budget, '/' )  
inputsum (Budget, '+T' )  
inputsum (Budget, '+A' )
```

Set analysis and set expressions

Set analysis offers a way of defining a set (or group) of data values that is different from the normal set defined by the current selections.

Normally, when you make a selection, aggregation functions, such as **Sum**, **Max**, **Min**, **Avg**, and **Count** aggregate over the selections that you have made: the current selections. Your selections automatically define the data set to aggregate over. With set analysis you can define a group that is independent of the current selections. This can be useful if you want to show a particular value, for example, the market share of a product across all regions, irrespective of the current selections.

Set analysis is also powerful when making different sorts of comparisons, such as what are the best-selling products compared with poorly-selling products, or this year against last year.

Let us imagine an example in which you start working in a document by selecting the year 2010 in a list box. The aggregations are then based on that selection, and the charts only show values for that year. When you make new selections, the charts are updated accordingly. The aggregations are made over the set of possible records defined by the current selections. With set analysis, you can define a set that is of interest to you and does not depend on the selections.

Creating set expressions

Before looking at the different parts of a set analysis example, there is a distinction that should be made between a set expression and set analysis:

Defining a set of field values is referred to as defining a set expression, whereas using set expressions to analyze data is referred to as set analysis. Consequently, the rest of this section focuses on the set expression and its components.

Here is a set analysis example: `sum({$<Year={2009}>} Sales)`, in which `{$<Year={2009}>}` is a set expression.

Set expressions can be used inside and outside aggregation functions, and are enclosed in curly brackets.

Example: Inner set expression

```
sum( {$<Year={2021}>} Sales )
```

Example: Outer set expression

```
{<Year={2021}>} Sum(Sales) / Count(distinct Customer)
```

For more information about inner and outer set expressions, see *Inner and outer set expressions*.

A set expression consists of a combination of the following parts:

- **Identifiers.** One or more identifiers define the relationship between the set expression and what is being evaluated in the rest of the expression. A simple set expression consists of a single identifier, such as the dollar sign, `{$}`, which means all records in the current selection.

- **Operators.** If there is more than one identifier, an operator or operators are used to refine the set of data by specifying how the sets of data represented by the identifiers are combined to create a subset or superset, for example.
- **Modifiers.** A modifier or modifiers can be added to the set expression to change the selection. A modifier can be used on its own or to modify an identifier to filter the data set.

Set expressions can only be used in expressions for charts, not in script expressions.

Identifiers, operators and modifiers are described in more detail in the following subsections.

Identifiers

Identifiers define the relationship between the set expression and the field values or expression being evaluated.

In our example `sum({$<Year={2009}>} sales)`, the identifier is the dollar sign, \$, and means that the set of records to be evaluated consists of the all the records of the current selection. This set is then further filtered by the modifier part of the set expression. In a more complex set expression, two identifiers can be combined using an operator.

The \$ set identifier is the same as not stating a set identifier. For instance, with the example above, the expression `sum({$<Year = {2009}>} sales)` is equivalent to `sum({<Year = {2009}>} sales)`.

This table shows some common identifiers.

Common identifiers

Identifier	Description
1	Represents the full set of all the records in the application, irrespective of any selections made.
\$ (or no set identifier)	Represents the records of the current selection. The set expression {\$} is thus the equivalent to not stating a set expression.
\$1	Represents the previous selection. \$2 represents the previous selection-but-one, and so on.
\$_1	Represents the next (forward) selection. \$_2 represents the next selection-but-one, and so on.
BM01	You can use any bookmark ID or bookmark name.
myAltstate	You can reference the selections made in an alternate state by its state name.

Examples:

Examples and results

Example	Result
<code>sum ({1} sales)</code>	Returns total sales for the document, disregarding selections but not the dimension.
<code>sum ({\$} sales)</code>	Returns the sales for the current selection, that is, the same as <code>sum(Sales)</code> .
<code>sum ({\$1} sales)</code>	Returns the sales for the previous selection.
<code>sum ({BM01} sales)</code>	Returns the sales for the bookmark named <i>BM01</i> .

Operators

Operators are used to include, exclude, or intersect parts of or whole data sets. All operators use sets as operands and return a set as result.

This table shows operators that can be used in set expressions.

Set operators

Operator	Description
+	Union. This binary operation returns a set consisting of the records that belong to any of the two set operands.
-	Exclusion. This binary operation returns a set of the records that belong to the first but not the other of the two set operands. Also, when used as a unary operator, it returns the complement set.
*	Intersection. This binary operation returns a set consisting of the records that belong to both of the two set operands.
/	Symmetric difference (XOR). This binary operation returns a set consisting of the records that belong to either, but not both of the two set operands.

Examples:

Examples and results

Example	Result
<code>sum({1-}\$ sales)</code>	Returns sales for everything excluded by the selection.
<code>sum({\$*BM01} sales)</code>	Returns sales for the intersection between the selection and bookmark <i>BM01</i> .
<code>sum({-(+\$BM01)} sales)</code>	Returns sales excluded by the selection and bookmark <i>BM01</i> .

Example	Result
<pre>sum({\$<Year= {2009}>+1<Country= {'Sweden'}>} Sales)</pre>	<p>Returns sales for the year 2009 associated with the current selections and add the full set of data associated with the country <i>Sweden</i> across all years.</p> <p>This expression uses the following set identifier: \$. Therefore, it is equivalent to this expression, which does not state a set identifier: <code>sum({<Year={2009}>+1<Country={'Sweden'}>} Sales)</code>.</p>

Modifiers

Modifiers are used to make additions or changes to a selection. Such modifications can be written in the set expression. A modifier consists of one or several field names, each followed by one or several selections that can be made in the field. Modifiers begin and end with angle brackets, <>.

A set modifier modifies the selection of the preceding set identifier. If no set identifier is referenced, the current selection state is implicit.

Examples:

Examples and results

MyField	Result
<pre>sum({\$<OrderDate = DeliveryDate>} Sales)</pre>	<p>Returns the sales for the current selection where OrderDate = DeliveryDate.</p> <p>This expression uses the following set identifier: \$. Therefore, it is equivalent to this expression, which does not state a set identifier: <code>sum({<OrderDate = DeliveryDate>} Sales)</code>.</p>
<pre>sum({1<Region = {US}>} Sales)</pre>	<p>Returns the sales for region US, disregarding the current selection.</p>
<pre>sum({\$<Region = >} Sales)</pre>	<p>Returns the sales for the selection, but with the selection in <i>Region</i> removed.</p> <p>This expression uses the following set identifier: \$. Therefore, it is equivalent to this expression, which does not state a set identifier: <code>sum({<Region = >} Sales)</code>.</p>
<pre>sum({<Region = >} Sales)</pre>	<p>Returns the same as the example above. When the set identifier to modify is omitted, the inherited state is assumed.</p>
<pre>sum({\$<Year= {2000}, Region= {"U*"}>} Sales)</pre>	<p>Returns the sales for the current selection, but with new selections both in <i>Year</i> and in <i>Region</i>.</p> <p>This expression uses the following set identifier: \$. Therefore, it is equivalent to this expression, which does not state a set identifier: <code>sum({<Year={2000}, Region={"U*"}>} Sales)</code>.</p>

Syntax for sets

The full syntax (not including the optional use of standard brackets to define precedence) is described using Backus-Naur Formalism:

```
set_expression ::= { set_entity { set_operator set_entity } }
```

```
set_entity ::= set_identifier [ set_modifier ]
set_identifier ::= 1 | $ | $N | $_N | bookmark_id | bookmark_name
set_operator ::= + | - | * | /
set_modifier ::= < field_selection {, field_selection } >
field_selection ::= field_name [ = | += | -= | *= | /= ] element_set_
expression
element_set_expression ::= element_set { set_operator element_set }
element_set ::= [ field_name ] | { element_list } | element_function
element_list ::= element { , element }
element_function ::= ( P | E ) ( [ set_expression ] [ field_name ] )
element ::= field_value | " search_mask "
```

Set modifiers

A set can be modified by an additional or a changed selection. Such a modification can be written in the set expression.

The modifier consists of one or several field names, each followed by a selection that should be made on the field, all enclosed by < and >. For example: <Year={2007,+2008},Region={US}>. Field names and field values can be quoted as usual, e.g. <[Sales Region]='west coast', 'South America'>.

A set modifier modifies the selection of the preceding set identifier. If no set identifier is referenced, the current selection state is implicit.

There are several ways to define the selection as described in the following.

Based on another field

A simple case is a selection based on the selected values of another field, for example <OrderDate = DeliveryDate>. This modifier will take the selected values from **DeliveryDate** and apply those as a selection on **OrderDate**. If there are many distinct values - more than a couple of hundred - then this operation is CPU intense and should be avoided.

Based on element sets

The most common example of a set expression is one that is based on a list of field values enclosed in curly brackets. The values are separated by commas, for example <Year = {2007, 2008}>. The curly brackets define an element set, where the elements can be either explicit field values or searches of field values.

Unless the listed values contain blanks or special characters, quotes are not needed. The listed values will simply be matched with the field values. This comparison is case insensitive.

If the listed values contain blanks or special characters, or if you want to use wild cards, then you need to enclose the values in quotation marks. Single quotes should be used if the listed values are explicit field values. Then case sensitive matches between the listed values and the individual field values will be made.

Double quotes should be used for searches, i.e. strings that contain wild cards or start with a relational operator or an equals sign. For example, <Ingredient = {"*Garlic*"}> will select all ingredients that contain the string 'Garlic'. Double quotes can be substituted with brackets, for example, <Ingredient = {[*Garlic*]}>. Double quotes can also be substituted with grave accents, for example <Ingredient = {`*Garlic*`}>. Searches are case-insensitive.

In previous versions of QlikView, there was no distinction between single quotes and double quotes and all quoted strings were treated as searches. To maintain backward compatibility, documents created with older versions of QlikView will continue to work as they did in previous versions. Documents created with QlikView November 2017 or later will respect the difference between the two types of quotes.

Forced exclusion

Finally, for fields in and-mode, there is also the possibility of forced exclusion. If you want to force exclusion of specific field values, you will need to use “~” in front of the field name.

Examples and results:

Example results

Examples	Results
<code>sum({1<Region={USA} >} Sales)</code>	Returns the sales for the region USA disregarding the current selection
<code>sum({\$<Region = >} Sales)</code>	Returns the sales for the current selection, but with the selection in 'Region' removed
<code>sum({<Region = >} Sales)</code>	Returns the same as the example immediately above. When the set to modify is omitted, \$ is assumed.
<div style="border: 1px solid #ccc; padding: 10px; margin: 10px 0;"> <p><i>The syntax in the two previous examples is interpreted as “no selections” in 'Region', that is to say all regions given other selections will be possible. It is not equivalent to the syntax <Region = {}> (or any other text on the right side of the equal sign implicitly resulting in an empty element set) which is interpreted as no region.</i></p> </div>	
<code>sum({\$<Year = {2000}, Region = {US, SE, DE, UK, FR}>} Sales)</code>	Returns the sales for current selection, but with new selections both in 'Year' and in 'Region'.
<code>sum({\$<~Ingredient = {"*garlic"}>} Sales)</code>	The field <i>Ingredient</i> is in AND mode. Returns the sales for current selection, but with a forced exclusion of all ingredients containing the string 'garlic'.
<code>sum({\$<Year = {"2*"}>} Sales)</code>	Returns the sales for the current selection, but with all years beginning with the digit “2”, i.e. most likely year 2000 and onwards, selected in the field 'Year'.
<code>sum({\$<Year = {"2*", "198*"}>} Sales)</code>	As above, but now also the 1980:s are included in the selection.

Examples	Results
<pre>sum({\$<Year = {>1978<2004}>} Sales)</pre>	Returns the sales for the current selections, but with a numeric search used to scope the range of years to sum the sales across.

If you want to force the exclusion of specific field values in objects such as text objects, you have to modify the script syntax. For example, if your script statement is the following:

```
=count({<ANDActor=>}DISTINCT Title)
```

Modify it as follows:

```
=count({<~ANDActor=, ANDActor=>} DISTINCT Title)
```

Set modifiers with set operators

The selection within a field can be defined using set operators working on different element sets. For example the modifier `<Year = {"20*", 1997} - {2000}>` will select all years beginning with "20" in addition to "1997", except for "2000".

Examples and results:

Examples and results

Example	Result
<pre>sum({\$<Product = Product + {OurProduct1} - {OurProduct2} >} Sales)</pre>	Returns the sales for the current selection, but with the product "OurProduct1" added to the list of selected products and "OurProduct2" removed from the list of selected products.
<pre>sum({\$<Year = Year + ({"20*", 1997} - {2000}) >} Sales)</pre>	Returns the sales for the current selection but with additional selections in the field "Year": 1997 and all that begin with "20" - however, not 2000. Note that if 2000 is included in the current selection, it will still be included after the modification.
<pre>sum({\$<Year = (Year + {"20*", 1997}) - {2000} >} Sales)</pre>	Returns almost the same as above, but here 2000 will be excluded, also if it initially is included in the current selection. The example shows the importance of sometimes using brackets to define an order of precedence.
<pre>sum({\$<Year = {"*"} - {2000}, Product = {"*bearing*"} >} Sales)</pre>	Returns the sales for the current selection but with a new selection in "Year": all years except 2000; and only for products containing the string 'bearing'.

Set modifiers using assignments with implicit set operators

This notation defines new selections, disregarding the current selection in the field. However, if you want to base your selection on the current selection in the field and add field values, for example you may want a modifier `<Year = Year + {2007, 2008}>`. A short and equivalent way to write this is `<Year += {2007, 2008}>`, i.e. the assignment operator implicitly defines a union. Also implicit intersections, exclusions and symmetric differences can be defined using `"*="`, `"-="` and `"/="`.

Examples:

Examples and results

Example	Result
<code>sum({\$<Product += {OurProduct1, OurProduct2} >} Sales)</code>	Returns the sales for the current selection, but using an implicit union to add the products 'OurProduct1' and 'OurProduct2' to the list of selected products.
<code>sum({\$<Year += {"20*", 1997} - {2000} >} Sales)</code>	Returns the sales for the current selection but using an implicit union to add a number of years in the selection: 1997 and all that begin with "20" - however, not 2000. Note that if 2000 is included in the current selection, it will still be included after the modification. Same as <code><Year=Year + ({"20*", 1997}-{2000})></code> .
<code>sum({\$<Product *= {OurProduct1} >} Sales)</code>	Returns the sales for the current selection, but only for the intersection of currently selected products and the product OurProduct1.

Set modifiers with advanced searches

Advanced searches using wild cards and aggregations can be used to define sets.

Examples:

Examples and results

Example	Result
<code>sum({\$-1<Product = {"*Internal*", "*Domestic*"}>} Sales)</code>	Returns the sales for current selection, excluding transactions pertaining to products with the string 'Internal' or 'Domestic' in the product name.
<code>sum({\$<Customer = {"=Sum ({1<Year = {2007}>} Sales) > 1000000"}>} Sales)</code>	Returns the sales for current selection, but with a new selection in the 'Customer' field: only customers who during 2007 had a total sales of more than 1000000.

Set modifiers with dollar-sign expansions

Variables and other dollar-sign expansions can be used in set expressions.

Examples:

Examples and results

Example	Result
sum({\$<Year = {#vLastYear}>} Sales)	Returns the sales for the previous year in relation to current selection. Here, a variable vLastYear containing the relevant year is used in a dollar-sign expansion.
sum({\$<Year = {#=Only(Year)- 1}>} Sales)	Returns the sales for the previous year in relation to current selection. Here, a dollar-sign expansion is used to calculate previous year.

Set modifiers with implicit field value definitions

The following describes how to define a set of field values using a nested set definition.

In such cases, the element functions P() and E() must be used, representing the element set of possible values and the excluded values of a field, respectively. Inside the brackets, it is possible to specify one set expression and one field, for example P({1} Customer). These functions cannot be used in other expressions:

Examples:

Examples and results

Example	Result
sum({<Customer = P({1<Product= {'Shoe'}>} Customer)>} Sales)	Returns the sales for current selection, but only those customers that ever have bought the product 'Shoe'. The element function P() here returns a list of possible customers; those that are implied by the selection 'Shoe' in the field Product.
sum({<Customer = P({1<Product= {'Shoe'}>})>} Sales)	Same as above. If the field in the element function is omitted, the function will return the possible values of the field specified in the outer assignment.
sum({<Customer = P({1<Product= {'Shoe'}>} Supplier)>} Sales)	Returns the sales for current selection, but only those customers that ever have supplied the product 'Shoe'. The element function P() here returns a list of possible suppliers; those that are implied by the selection 'Shoe' in the field Product. The list of suppliers is then used as a selection in the field Customer.

Example	Result
<pre>sum({<Customer = E({1<Product= {'Shoe'}>})>} Sales)</pre>	Returns the sales for current selection, but only those customers that never bought the product 'Shoe'. The element function E() here returns the list of excluded customers; those that are excluded by the selection 'Shoe' in the field Product.

Inner and outer set expressions

Set expressions can be used inside and outside aggregation functions, and are enclosed in curly brackets.

When you use a set expression inside an aggregation function, it can look like this:

Example: Inner set expression

```
sum( {<Year={2021}>} Sales )
```

Use a set expression outside the aggregation function if you have expressions with multiple aggregations and want to avoid writing the same set expression in every aggregation function.

If you use an outer set expression, it must be placed at the beginning of the scope.

Example: Outer set expression

```
{<Year={2021}>} sum(Sales) / Count(distinct Customer)
```

If you use a set expression outside the aggregation function, you can also apply it on existing master measures.

Example: Outer set expression applied to master measure

```
{<Year={2021}>} [Master Measure]
```

A set expression used outside aggregation functions affects the entire expression, unless it is enclosed in brackets then the brackets define the scope. In the lexical scoping example below, the set expression is only applied to the aggregation inside the brackets.

Example: Lexical scoping

```
( {<Year={2021}>} sum(Amount) / Count(distinct Customer) ) - Avg(CustomerSales)
```

Rules

Lexical scope

The set expression affects the entire expression, unless it is enclosed in brackets. If so, the brackets define the lexical scope.

Position

The set expression must be placed in the beginning of the lexical scope.

Context

The context is the selection that is relevant for the expression. Traditionally, the context has always been the default state of current selection. But if an object is set to an alternate state, the context is the alternate state of the current selection.

You can also define a context in the form of an outer set expression.

Inheritance

Inner set expressions have precedence over outer set expressions. If the inner set expression contains a set identifier, it overrides the context defined in the outer set expression. Otherwise, the inner and outer set expressions are both evaluated.

Example 1: Inner set expression with set identifier

```
{<Year={2023}>} Sum(Sales) / Count({1} distinct OrderNumber)
```

In the above expression, the inner set expression `Count({1} distinct OrderNumber)` consists of the set identifier `{1}`. When this inner set expression is evaluated, the scope defined in the outer set expression `{<Year={2023}>}` is not applied.

Example 2: Inner set expressions without set identifiers

```
{<Year={2023}>} Sum ({<Status={'Confirmed'}>} Sales_Stream1) + Sum ({<UpdatedStatus={'Confirmed'}>} Sales_Stream2)
```

In the above expression, the inner set expressions `sum ({<Status={'Confirmed'}>} Sales_Stream1)` and `sum ({<UpdatedStatus={'Confirmed'}>} Sales_Stream2)` do not contain set identifiers. Therefore, the outer set expression `{<Year={2023}>}` and both inner set expressions are all applied when evaluating the result.

Element set assignment

The element set assignment determines how the two selections are merged. If a normal equals sign is used, the selection in the inner set expression has precedence. Otherwise, the implicit set operator will be used.

- `{<Field={value}>}` - this inner selection replaces any outer selection in “Field”.
- `{<Field+={value}>}` - this inner selection is merged with the outer selection in “Field”, using the union operator.
- `{<Field*={value}>}` - this inner selection is merged with the outer selection in “Field”, using the intersection operator.

Element set assignment

The element set assignment determines how the two selections are merged. If a normal equals sign is used, the selection in the inner set expression has precedence. Otherwise, the implicit set operator will be used.

- {<Field={value}>} - this inner selection replaces any outer selection in "Field".
- {<Field+={value}>} - this inner selection is merged with the outer selection in "Field", using the union operator.
- {<Field*={value}>} - this inner selection is merged with the outer selection in "Field", using the intersection operator.

Inheritance in multiple steps

The inheritance can occur in multiple steps. Examples:

- Current Selection → Sum(Amount)
The aggregation function will use the context, which here is the current selection.
- Current Selection → {<Set1>} Sum(Amount)
set1 will inherit from current selection, and the result will be the context for the aggregation function.
- Current Selection → {<Set1>} ({<Set2>} Sum(Amount))
set2 will inherit from set1, which in turn inherits from current selection, and the result will be the context for the aggregation function.

The Aggr() function

The Aggr() function creates a nested aggregation that has two independent aggregations. In the example below, a Count() is calculated for each value of Dim, and the resulting array is aggregated using the sum() function.

Example:

```
Sum(Aggr(Count(X),Dim))
```

Count() is the inner aggregation and sum() is the outer aggregation.

- The inner aggregation does not inherit any context from the outer aggregation.
- The inner aggregation inherits the context from the Aggr() function, which may contain a set expression.
- Both the Aggr() function and the outer aggregation function inherit the context from an outer set expression.

Chart expression and aggregation syntax

The syntax used for chart (chart) expressions and aggregations is described in the following sections.

General syntax for chart expressions

The following general syntax structure can be used for chart expressions, with many optional parameters:

```
expression ::= ( constant | expressionname | operator1 expression | expression operator2  
expression | function | aggregation function | (expression) )
```

where:

constant is a string (a text, a date or a time) enclosed by single straight quotation marks, or a number. Constants are written without thousands separator and with a decimal point as decimal separator.

expressionname is the name (label) of another expression in the same chart.

operator1 is a unary operator (working on one expression, the one to the right).

operator2 is a binary operator (working on two expressions, one on each side).

```
function ::= functionname ( parameters )
parameters ::= expression { , expression }
```

The number and types of parameters are not arbitrary. They depend on the function used.

```
aggregationfunction ::= aggregationfunctionname ( parameters2 )
parameters2 ::= aggexpression { , aggexpression }
```

The number and types of parameters are not arbitrary. They depend on the function used.

General syntax for aggregations

The following general syntax structure can be used for aggregations, with many optional parameters:

```
aggexpression ::= ( fieldref | operator1 aggexpression | aggexpression operator2
aggexpression | functioninagr | ( aggexpression ) )
```

fieldref is a field name.

```
functionagr ::= functionname ( parameters2 )
```

Expressions and functions can thus be nested freely, as long as **fieldref** is always enclosed by exactly one aggregation function and provided the expression returns an interpretable value, QlikView does not give any error messages.

Examples of Aggregate Qualifiers

These examples are made with the *Sum - chart function (page 1069)* function, but may be applied on all chart aggregation functions supporting set analysis definitions and the **total** qualifier.

Example 1:

Study the representation of a straight table below, depicting the logical state before any selections have been made:

Aggregation function with total qualifier				
Month	Group	Sum(Value)	sum(total Value)	sum({1} total Value)
		21	21	21
1	A	1	21	21
1	B	2	21	21
2	A	3	21	21
2	B	4	21	21
3	A	5	21	21
3	B	6	21	21

Example table: Aggregation function with total qualifier

Month	Group	Sum(Value)	sum(total Value)	sum({1} total Value)
-	-	21	21	21
1	A	1	21	21
1	B	2	21	21

9 Script syntax and chart functions

Month	Group	Sum(Value)	sum(total Value)	sum({1} total Value)
2	A	3	21	21
2	B	4	21	21
3	A	5	21	21
3	B	6	21	21

The second and third expression column have the same number in all rows. This number equals the calculated total in the first expression column.

Now, let's select months 1 and 2 only. The result is as follows:

Aggregation function with total qualifier				
Month	Group	Sum(Value)	sum(total Value)	sum({1} total Value)
		10	10	21
1	A	1	10	21
1	B	2	10	21
2	A	3	10	21
2	B	4	10	21

Example table: Aggregation function with total qualifier, filtered by month

Month (Filter: 1-2)	Group	Sum(Value)	sum(total Value)	sum({1} total Value)
-	-	10	10	21
1	A	1	10	21
1	B	2	10	21
2	A	3	10	21
2	B	4	10	21

The result of the third expression (fifth column) remains unchanged because the **set** definition disregards current selections. The second expression (fourth column) with the **total** qualifier, shows the new total 10, which is still equivalent to the first expression total (third column).

Example 2:

Study the representation of a straight table below:

total qualifier with listed fields				
Month	Group	Sum(Value)	sum(total <Month> Value)	sum(total <Group> Value)
		21	21	21
1	A	1	3	9
1	B	2	3	12
2	A	3	7	9
2	B	4	7	12
3	A	5	11	9
3	B	6	11	12

Example table: Total qualifier with listed fields

Month	Group	Sum(Value)	sum(total <Month> Value)	sum(total <Group> Value)
-	-	21	21	21
1	A	1	3	9
1	B	2	3	12
2	A	3	7	9
2	B	4	7	12
3	A	5	11	9
3	B	6	11	12

In the third expression column (`sum(total<Month> val)`) one total is calculated for each month.

In the fourth expression column (`sum(total<Grp> val)`) one total is calculated for each group.

See also:

p *Set analysis and set expressions (page 1008)*

p *Sum of rows in pivot tables (page 1221)*

p *AggrAggr()* returns an array of values for the expression calculated over the stated dimension or dimensions. For example, the maximum value of sales, per customer, per region. The Aggr function is used for nested aggregations, in which its first parameter (the inner aggregation) is calculated once per dimensional value. The dimensions are specified in the second parameter (and subsequent parameters). In addition, the Aggr function should be enclosed in an outer aggregation function, using the array of results from the Aggr function as input to the aggregation in which it is nested `Aggr({SetExpression} [DISTINCT] [NODISTINCT] expr, StructuredParameter{, StructuredParameter})` dual expr: An expression consisting of an aggregation function. By default, the aggregation function will aggregate over the set of possible records defined by the selection. **StructuredParameter**: StructuredParameter consists of a dimension and optionally, sorting criteria in the format: `(Dimension(Sort-type, Ordering))`. The dimension is a single field and cannot be an expression. The dimension is used to determine the array of values the Aggr expression is calculated for. If sorting criteria are included, the array of values created by the Aggr function, calculated for the dimension, is sorted. This is important when the sort order affects the result of the expression the Aggr function is enclosed in. For details of how to use sorting criteria, see *Adding sorting criteria to the dimension in the structured parameter*. **SetExpression**: By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression. **DISTINCT**: If the expression argument is preceded by the distinct qualifier or if no qualifier is used at all, each distinct combination of dimension values will generate only one return value. This is the normal way aggregations are made - each distinct combination of dimension values will render one line in the chart. **NODISTINCT**: If the expression argument is preceded by the nodistinct qualifier, each combination of dimension values may generate more than one return value, depending on underlying data structure. If there is only one dimension, the aggr function will return an array with the same number of elements as there are rows in the source data. Basic aggregation functions, such as Sum, Min, and Avg, return a single numerical value whereas the Aggr() function can be

9 Script syntax and chart functions

compared to creating a temporary staged result set (a virtual table) over which another aggregation can be made. For example, by computing an average sales value by summing the sales by customer in an Aggr() statement and then calculating the average of the summed results: Avg(TOTAL Aggr(Sum(Sales), Customer)). Use the Aggr() function in calculated dimensions if you want to create nested chart aggregation in multiple levels. Each dimension in an Aggr() function must be a single field, and cannot be an expression (calculated dimension). Adding sorting criteria to the dimension in the structured parameter

In its basic form, the argument StructuredParameter in the Aggr function syntax is a single dimension. The expression: Aggr(Sum(Sales, Month)) finds the total value of sales for each month. However, when enclosed in another aggregation function, there can be unexpected results unless sorting criteria are used. This is because some dimensions can be sorted numerically or alphabetically, and so on. In the StructuredParameter argument in the Aggr function, you can specify sorting criteria on the dimension in your expression. This way, you impose a sort order on the virtual table that is produced by the Aggr function. The argument StructuredParameter has the following syntax: (FieldName, (Sort-type, Ordering)) Structured parameters can be nested: (FieldName, (FieldName2, (Sort-type, Ordering))) Sort-type can be: NUMERIC, TEXT, FREQUENCY, or LOAD_ORDER. The ordering types associated with each Sort-type are as follows:

Sort type	Available ordering types
NUMERIC	ASCENDING, DESCENDING, or REVERSE
TEXT	ASCENDING, A2Z, DESCENDING, REVERSE, or Z2A
FREQUENCY	ASCENDING, ORIGINAL, DESCENDING, or REVERSE
LOAD_ORDER	ASCENDING and ORIGINAL

The ordering types REVERSE and DESCENDING are equivalent. For Sort-type TEXT, the ordering types ASCENDING and A2Z are equivalent, and DESCENDING, REVERSE, and Z2A are equivalent. For Sort-type LOAD_ORDER, the ordering types ASCENDING and ORIGINAL are equivalent.

Examples Avg(Aggr(Sum(UnitSales*UnitPrice), Customer)) The expression Aggr(Sum(UnitSales*UnitPrice), Customer) finds the total value of sales by Customer, and returns an array of values: 295, 715, and 120 for the three Customer values. Effectively, we have built a temporary list of values without having to create an explicit table or column containing those values. These values are used as input to the Avg() function to find the average value of sales, 376.6667. (You must have Totals selected under Presentation in the properties panel. Aggr(NODISTINCT Max(UnitPrice), Customer) An array of values: 16, 16, 16, 25, 25, 25, 19, and 19. The nodistinct qualifier means that the array contains one element for each row in the source data: each is the maximum UnitPrice for each Customer and Product.

max(aggr(sum(Customers)-above(Sum(Customers)), (MonthYear,(NUMERIC, ASCENDING)))) Using sorting criteria in the StructuredParameter argument in the expression: max(aggr(sum(Customers)-above(Sum(Customers)), (MonthYear,(NUMERIC, ASCENDING)))) Without sorting criteria the result of the expression max(aggr(sum(Customers)-above(Sum(Customers)), (MonthYear))) depends on how the dimension MonthYear is sorted. We might not get the result we want. By adding values for sort type and ordering type to the dimension, we give sorting criteria to the structured parameter: (MonthYear, (NUMERIC, ASCENDING)), where the sort type NUMERIC and ordering ASCENDING determine that MonthYear is sorted in ascending numerical order. Here, we are looking to find the greatest increase in number of customers, month-on-month. This could be used in a KPI visualization, for example. The Aggr part of the expression compares the total number of customers in one month (given by MonthYear) to the total number in the previous month. Because we use sorting criteria with the dimension: (MonthYear, (NUMERIC, ASCENDING)), we are sure that Aggr compares the numbers of customers in consecutive months in the virtual table by sorting the months in ascending numerical order, and not in ascending alphabetical order.

Data used in examples: Create a table with Customer, Product, UnitPrice, and UnitSales as dimensions. Add the expression to the table, as a measure.

```
ProductData:LOAD * inline [Customer|Product|UnitSales|UnitPriceAstrida|AA|4|16Astrida|AA|10|15Astrida|BB|9|9Betacab|BB|5|10Betacab|CC|2|20Betacab|DD|25|25Canutility|AA|8|15Canutility|CC|19] (delimiter is '|');
```

(page 1)

Examples of concat functions

The **CONCAT()** function should not be confused with the **CONCATENATE** script keyword.

In its simplest form, **Concat()** is used to string / join together values/words/selections into one string. However, it can be utilized in a number of ways to help you solve different problems. All the examples are based upon the following table:

Table	MyColumn	Date	Value
Data	JKL	01/01/2012	11
Data1	VWX	01/02/2012	13
Data	GHI	01/03/2012	13
Data	ABC	01/04/2012	15
Data1	STU	01/05/2012	18
Data1	PQR	01/06/2012	10
Data1	MNO	01/07/2012	25
Data	DEF	01/08/2012	11

Example string table data

Table	MyColumn	Date	Value
Data	JKL	01/01/2012	11
Data1	VWX	01/02/2012	13
Data	GHI	01/03/2012	13
Data	ABC	01/04/2012	15
Data1	STU	01/05/2012	18
Data1	PQR	01/06/2012	10
Data1	MNO	01/07/2012	25
Data	DEF	01/08/2012	11

Simple String Concatenation

As mentioned earlier, the **concat** function lets you string together a list of values. These values can be hard coded or driven by selections/data.

```
=CONCAT(MyColumn, ',')
```

```
=CONCAT(DISTINCT MyColumn, ',')
```

This simple **concat** statement would string together all of the possible values from the column **MyColumn**. You may wish to add the **DISTINCT** keyword. This would ensure that each value is only displayed once in the string:

```
ABC, DEF, GHI, JKL, MNO, PQR, STU, VWX
```

When using a simple **concat**, you have the option to add a sort weight to the function to order the string values by a column of your choice. In the example below, the date column is added to sort the values.

```
=CONCAT(MyColumn, ', ', Date)
```

Result: JKL, VWX, GHI, ABC, STU, PQR, MNO, DEF

Concat() within an Expression/Set Statement

Example: Passing multiple dynamic values to a set analysis expression

There are occasions when you want to pass a dynamic selection of values to a set statement. To do this you need to add some single quotes to the string so that the **CONCAT()** function returns e.g. 'JKL','VWX'. But you cannot have the single quotes as they are, since they then would be interpreted when the **Concat** is evaluated instead of when the set expression is evaluated. Instead, use the **Chr()** function:

```
=CONCAT(Chr(39)&MyColumn&Chr(39),',')
```

You can then pass this **concat** statement to the inside of an expression:

```
=Sum({<MyColumn={$(=CONCAT(Chr(39)&MyColumn&Chr(39),','))}>} Value)
```

In most instances, this technique would be used where data islands are present. It lets you pass values to an expression that will not affect any part of the data model as the data island table is not joined to it.

Concat() in the Script

Concat can also be used in the script to convert multiple rows into one single column value, just as any other aggregation.

Remembering the source data used earlier, the result of script side **CONCAT** is as follows:

```
ConcatExample:  
Load Table,  
Concat(MyColumn,',') as CombinedData  
Resident Temp  
Group By Table;
```

The following is the result of this script function:

Example output in table form

Table	CombinedData
Data	ABC,DEF,GHI,JKL
Data1	MNO,PQR,STU,WVX

Using Rank() to influence the Concat()

When you start to utilize other function in conjunction with **concat()** you can start to achieve clever results. In this example, **Rank()** has been used to grab the top three performers (based on Value) and string them together.

```
=CONCAT(IF(aggrr(Rank(sum(Value)),MyColumn)<=3,MyColumn),',')
```

Result: ABC, MNO, STU

Examples of Alternate States in Chart Expressions

These examples are intended to show best practices regarding the use of alternate states by QlikView Developers and/or extreme QlikView Power-Users. These examples can be found in the file: 'Alternate States Functionality.qvw'

Synchronizing Selections between States

The following expressions can be used in a single chart:

- `count({$} DISTINCT [Invoice Number])`
- `count({State1} DISTINCT [Invoice Number])`
- `count({State2} DISTINCT [Invoice Number])`

There is a problem with this method; the QlikView Developer must duplicate the selections (list boxes and multi boxes) for all three states so that the end-user can make appropriate selections for the various states. In many situations the QlikView Developer will want to have a set of 'common' selections available to all states. This will allow the end user to set the context for the various charts and then make use of specific selections to show the differences between states. Set Analysis can be used with states to keep certain selections consistent between states.

- `count({State1<Year = $::Year, Month = $::Month>} DISTINCT [Invoice Number])`
- `count({State2<Year = $::Year, Month = $::Month>} DISTINCT [Invoice Number])`

The QlikView Developer will keep the Year and Month selections in State1 and State2 synchronized with the Year and Month selections in the **default state**. The QlikView Developer can add elements to the set modifiers as necessary in order to keep even more fields consistent between states.

Set Operators

It is possible to use set operators (+, *, -, /) with states. The following expressions are valid and will count the distinct invoice numbers that are in either the **default state** or State1.

Examples:

- `count({$ + State1} DISTINCT [Invoice Number])`
counts the distinct invoice numbers in the union of the <default> state and State1.
- `count({1 - State1} DISTINCT [Invoice Number])`
counts the distinct invoice numbers not in State1.
- `count({State1 * State2} DISTINCT [Invoice Number])`
counts the distinct invoice numbers in that are in both the <default> state and State1.

Caution should be used when using set operators in this manner. In some situations the result will not be what is expected. This is because the selections in a given state generate a set of data that may not be fully compatible with the set(s) it is being combined with. This is especially true as the complexity of the data model increases.

Implicit Field Value Definitions

Another way of using set operators is with the element functions P() and E(). These functions are only available within set expressions.

Examples:

- `count({$<[Invoice Number] = p({State1} [Invoice Number])>} DISTINCT [Invoice Number])`

This expression counts the distinct invoice numbers in the <default> state based on the possible invoice numbers available in State1.

It is almost, but not quite equivalent to the following expression:

- `count({$<[Invoice Number] = State1::[Invoice Number]>} DISTINCT [Invoice Number])`

The difference between the expressions is that in the first one, the possible values on invoice number from State1 are passed into the **default state**. In the second expression, the selected values from State1 are passed into the **default state**. If the user has not made any invoice number selections in State1, no invoice number values will be passed into the **default state**.

Set operators are best used within set modifiers. The following expression finds the intersection of the possible invoice numbers from State1 and State2 and passes those values into the invoice numbers in the **default state**.

Examples:

- `count({$<[Invoice Number] = p({State1} [Invoice Number]) * p({State2} [Invoice Number])>} DISTINCT [Invoice Number])`

The expression to find the intersection of invoice numbers in the <default> state and State1 is:

- `count({$<[Invoice Number] = p({$} [Invoice Number]) * p({State1} [Invoice Number])>} DISTINCT [Invoice Number])`

This expression may seem confusing because it uses a state (<default> in this instance) in both the element function and a set identifier. Keep in mind that the element function p(\$) is returning the possible values in the **default state**. The set/state identifier {\$} is being modified by the result of the element functions. Any invoice selections currently existing in the **default state** are being overridden by the values from the intersection of the element functions.

It should be noted that the above expression is still not completely correct as it fails to synchronize the common selections between the **default state** and State1. Below is an expression that will do so:

Examples:

- ```
count({$<[Invoice Number] = p({$} [Invoice Number]) * p({State<Year = $::Year, Month = $::Month>} [Invoice Number])>} DISTINCT [Invoice Number])
```

As before, the QlikView Developer can add fields into the modifier to keep selections consistent between various states.

### Examples of Chart Ranking functions

These examples are made with the **rank (VRank)** function, but may be applied in a similar manner to the **HRank** function. However, note that the **HRank** function is relevant only to pivot tables.

#### Example 1:

Study the two one-dimensional straight tables below:

| Single dimension RANK |          |                |
|-----------------------|----------|----------------|
| Month                 | sum(Val) | rank(sum(Val)) |
|                       | 110      | -              |
| 1                     | 17       | 3              |
| 2                     | 9        | 7              |
| 3                     | 22       | 1              |
| 4                     | 16       | 4              |
| 5                     | 10       | 6              |
| 6                     | 5        | 8              |
| 7                     | 11       | 5              |
| 8                     | 20       | 2              |

| Sorted by ranking column |          |                |
|--------------------------|----------|----------------|
| Month                    | sum(Val) | rank(sum(Val)) |
|                          | 110      | -              |
| 3                        | 22       | 1              |
| 8                        | 20       | 2              |
| 1                        | 17       | 3              |
| 4                        | 16       | 4              |
| 7                        | 11       | 5              |
| 5                        | 10       | 6              |
| 2                        | 9        | 7              |
| 6                        | 5        | 8              |

## 9 Script syntax and chart functions

---

Example table: Single dimension Rank

| Month | sum(Val) | rank(sum(Val)) |
|-------|----------|----------------|
| -     | 110      | -              |
| 1     | 17       | 3              |
| 2     | 9        | 7              |
| 3     | 22       | 1              |
| 4     | 16       | 4              |
| 5     | 10       | 6              |
| 6     | 5        | 8              |
| 7     | 11       | 5              |
| 8     | 20       | 2              |

Example table: Single dimension rank, sorted by ranking column

| Month | sum(Val) | rank(sum(Val)) |
|-------|----------|----------------|
| -     | 110      | -              |
| 3     | 22       | 1              |
| 8     | 20       | 2              |
| 1     | 17       | 3              |
| 4     | 16       | 4              |
| 7     | 11       | 5              |
| 5     | 10       | 6              |
| 2     | 9        | 7              |
| 6     | 5        | 8              |

The two tables are the same, but the first one is sorted by the first column while the second one is sorted by the last column. This exemplifies the basic functionality of **rank**. The highest value has the highest rank (lowest ranking number).

The **rank** function always returns NULL in total rows.

### Example 2:

Study the two-dimensional pivot table below:

| Group | Month | sum(Val) | rank(sum(Val)) | rank(total sum(Val)) |
|-------|-------|----------|----------------|----------------------|
| A     | 1     | 17       | 2              | 3                    |
|       | 4     | 16       | 3              | 4                    |
|       | 7     | 11       | 4              | 5                    |
|       | 8     | 20       | 1              | 2                    |
|       | Total | 64       | -              | -                    |
| B     | 2     | 9        | 3              | 7                    |
|       | 3     | 22       | 1              | 1                    |
|       | 5     | 10       | 2              | 6                    |
|       | 6     | 5        | 4              | 8                    |
|       | Total | 46       | -              | -                    |
| Total | -     | 110      | -              | -                    |

Example table: Two dimension Rank and the effect of total

| Group | Month | sum(Val) | rank(sum(Val)) | rank(total sum(Val)) |
|-------|-------|----------|----------------|----------------------|
| A     | 1     | 17       | 2              | 3                    |
| A     | 4     | 16       | 3              | 4                    |
| A     | 7     | 11       | 4              | 5                    |
| A     | 8     | 20       | 1              | 2                    |
| A     | Total | 64       | -              | -                    |
| B     | 2     | 9        | 3              | 7                    |
| B     | 3     | 22       | 1              | 1                    |
| B     | 5     | 10       | 2              | 6                    |
| B     | 6     | 5        | 4              | 8                    |
| B     | Total | 46       | -              | -                    |
| Total | -     | 110      | -              | -                    |

This table is based on the same data as the two tables in the first example. It is now possible to see how the current column segment is the inner grouping in the multi-dimensional case. The Month field within group A is ranked separately from the Month field in group B. By introducing the **total** qualifier an overall ranking can again be achieved.

### Example 3:

This example will demonstrate the effect of the different modes for the numeric representation of the ranking. Study the table below:

| The effect of the mode parameter on the result number representation |        |              |        |        |        |        |        |
|----------------------------------------------------------------------|--------|--------------|--------|--------|--------|--------|--------|
| Month                                                                | sum(X) | rank(sum(X)) | mode=0 | mode=1 | mode=2 | mode=3 | mode=4 |
|                                                                      | 86     | -            | -      | -      | -      | -      | -      |
| 4                                                                    | 20     | 1            | 1      | 1      | 1      | 1      | 1      |
| 2                                                                    | 12     | 2-3          | 2      | 2      | 2.5    | 3      | 2      |
| 7                                                                    | 12     | 2-3          | 2      | 2      | 2.5    | 3      | 3      |
| 3                                                                    | 10     | 4-5          | 4.5    | 4      | 4.5    | 5      | 5      |
| 5                                                                    | 10     | 4-5          | 4.5    | 4      | 4.5    | 5      | 4      |
| 8                                                                    | 9      | 6            | 6      | 6      | 6      | 6      | 6      |
| 6                                                                    | 7      | 7            | 7      | 7      | 7      | 7      | 7      |
| 1                                                                    | 6      | 8            | 8      | 8      | 8      | 8      | 8      |

Example table: Effects of the mode parameter on result number representation

| Month | sum(X) | rank(sum(X)) | mode=0 | mode=1 | mode=2 | mode=3 | mode=4 |
|-------|--------|--------------|--------|--------|--------|--------|--------|
| -     | 86     | -            | -      | -      | -      | -      | -      |
| 4     | 20     | 1            | 1      | 1      | 1      | 1      | 1      |
| 2     | 12     | 2-3          | 2      | 2      | 2.5    | 3      | 2      |
| 7     | 12     | 2-3          | 2      | 2      | 2.5    | 3      | 3      |
| 3     | 10     | 4-5          | 4.5    | 4      | 4.5    | 5      | 5      |
| 5     | 10     | 4-5          | 4.5    | 4      | 4.5    | 5      | 4      |
| 8     | 9      | 6            | 6      | 6      | 6      | 6      | 6      |
| 6     | 7      | 7            | 7      | 7      | 7      | 7      | 7      |
| 1     | 6      | 8            | 8      | 8      | 8      | 8      | 8      |

The third column shows the ranking in text representations while column 4 - 8 shows the number representation of the same ranking in different modes. The expression in each column is:

```
num(rank(sum(X), mode))
```

where `mode` is a value from 0 to 4:

- **Mode 0 (default)** Rows 2 and 3 share ranking but are clearly on the lower half of the total ranking. Their number representation is therefore rounded downwards to 2. Rows 4 and 5 share ranking too, but fall just above the middle of the ranking table. Therefore they get a number representation of the average of the first and the last rank in the column  $((1+8)/2=4.5)$ . This mode is especially useful when you want to use **Visual Cues** to mark the data ranking highest and lowest within a group.
- **Mode 1** In both cases the lower ranking figure within the group is used, i.e. 2 for rows 2 and 3, 4 for rows 4 and 5.
- **Mode 2** In both cases the average of the low and high ranking within the group is used, i.e. 2.5  $((2+3)/2)$  for rows 2 and 3, 4.5  $((4+5)/2)$  for rows 4 and 5.

## 9 Script syntax and chart functions

- **Mode 3** In both cases the higher ranking figure within the group is used, i.e. 3 for rows 2 and 3, 5 for rows 4 and 5.
- **Mode 4** Each row is assigned its own distinct numeric value. The order within groups sharing a ranking is determined by the sort order of the chart's dimensions.

### Example 4:

This example will demonstrate the effect of the different formats for the text representation of the ranking function. Study the table below:

| The effect of the format parameter on the result text representation |        |                  |                  |                  |
|----------------------------------------------------------------------|--------|------------------|------------------|------------------|
| Month                                                                | sum(X) | rank(sum(X),0,0) | rank(sum(X),0,1) | rank(sum(X),0,2) |
|                                                                      | 86     | -                | -                | -                |
| 4                                                                    | 20     | 1                | 1                | 1                |
| 2                                                                    | 12     | 2-3              | 2                | 2                |
| 7                                                                    | 12     | 2-3              | 2                |                  |
| 3                                                                    | 10     | 4-5              | 4                |                  |
| 5                                                                    | 10     | 4-5              | 4                | 4                |
| 8                                                                    | 9      | 6                | 6                | 6                |
| 6                                                                    | 7      | 7                | 7                | 7                |
| 1                                                                    | 6      | 8                | 8                | 8                |

Example table: Effect of the format parameter on result text representation

| Month | sum(X) | rank(sum(X),0,0) | rank(sum(X),0,1) | rank(sum(X),0,2) |
|-------|--------|------------------|------------------|------------------|
| -     | 86     | -                | -                | -                |
| 4     | 20     | 1                | 1                | 1                |
| 2     | 12     | 2-3              | 2                | 2                |
| 7     | 12     | 2-3              | 2                | -                |
| 3     | 10     | 4-5              | 4                | -                |
| 5     | 10     | 4-5              | 4                | 4                |
| 8     | 9      | 6                | 6                | 6                |
| 6     | 7      | 7                | 7                | 7                |
| 1     | 6      | 8                | 8                | 8                |

Columns 3 - 5 show the text representation of the same ranking function with different `format` values, where `format` is a value from 0 to 2:

- **Format 0 (default)** Rows sharing ranking are shown as 'low value - high value', e.g. '2 - 3' and '4 - 5'.
- **Format 1** Rows sharing ranking always get the number of the lowest rank as text representation, in this case e.g. 2 for rows 2 and 3.

- **Format 2** One row in each group sharing the same ranking gets the low rank number as text representation, while the other rows within the group get a blank string. The order within the groups sharing a ranking is determined by the sort order of the chart's dimensions.

### Examples of Chart Inter Record functions

#### Top Function Examples

These examples are made with the **top** function, but may be applied in a similar manner to the **bottom**, **first** and **last** functions. However, note that the **first** and **last** functions are relevant only to pivot tables.

#### Example 1:

Study the straight table below, depicting the use of the **top** function in a one-dimensional table:

| Single dimension straight table - top |          |               |                        |
|---------------------------------------|----------|---------------|------------------------|
| Month                                 | sum(Val) | top(sum(Val)) | sum(Val)/top(sum(Val)) |
|                                       | 21       | 3             | 700%                   |
| 1                                     | 3        | 3             | 100%                   |
| 2                                     | 7        | 3             | 233%                   |
| 3                                     | 11       | 3             | 367%                   |

Example table: One dimensional straight table with top function

| Month | sum(Val) | top(sum(Val)) | sum(Val) / top(sum(Val)) |
|-------|----------|---------------|--------------------------|
| -     | 21       | 3             | 700%                     |
| 1     | 3        | 3             | 100%                     |
| 2     | 7        | 3             | 233%                     |
| 3     | 11       | 3             | 367%                     |

In the single dimension case, the **top** function will always refer to the first data row of the table ( The total row is not included.)

Note that expressions using the **top** function will be properly evaluated in the total row too since the total has a clear relation to a specific column segment, in this case the entire column.

#### Example 2:

Below is a two-dimensional straight table sorted primarily on the field Grp.

| Month | Grp | sum(Val) | top(sum(Val)) | top(total sum(Val)) |
|-------|-----|----------|---------------|---------------------|
|       |     | 21       | -             | 1                   |
| 1     | A   | 1        | 1             | 1                   |
| 2     | A   | 3        | 1             | 1                   |
| 3     | A   | 5        | 1             | 1                   |
| 1     | B   | 2        | 2             | 1                   |
| 2     | B   | 4        | 2             | 1                   |
| 3     | B   | 6        | 2             | 1                   |

Example table: Two dimensional straight table with total qualifier

| Month | Grp | sum(Val) | top(sum(Val)) | top(total sum(Val)) |
|-------|-----|----------|---------------|---------------------|
| -     | -   | 21       | -             | 1                   |
| 1     | A   | 1        | 1             | 1                   |
| 2     | A   | 3        | 1             | 1                   |
| 3     | A   | 5        | 1             | 1                   |
| 1     | B   | 2        | 2             | 1                   |
| 2     | B   | 4        | 2             | 1                   |
| 3     | B   | 6        | 2             | 1                   |

The **top** function without the **total** qualifier will now return the expression evaluated on the top row within the innermost sort group (Grp dimension in this case). One value will be returned for Grp = A and one for Grp = B.

By using the **total** qualifier in the multi dimension case, you may again refer to the absolute top row of the table with the same value being returned for all rows. The expression will of course be evaluated for the column segment spanning the entire column.

The expression using the **top** function without the **total** qualifier will evaluate to NULL in the total row, because it cannot be clearly associated with a specific column segment.

We will now convert the above straight table to a pivot table with all totals activated.

| Month | Grp   | sum(Val) | top(sum(Val)) | top(total sum(Val)) |
|-------|-------|----------|---------------|---------------------|
| 1     | A     | 1        | 1             | 1                   |
|       | B     | 2        | 1             | 1                   |
|       | Total | 3        | 1             | -                   |
| 2     | A     | 3        | 3             | 1                   |
|       | B     | 4        | 3             | 1                   |
|       | Total | 7        | 3             | -                   |
| 3     | A     | 5        | 5             | 1                   |
|       | B     | 6        | 5             | 1                   |
|       | Total | 11       | 5             | -                   |
| Total |       | 21       | -             | 1                   |

Example table: Two dimensional pivot table with total qualifier

| Month | Grp   | sum(Val) | top(sum(Val)) | top(total sum(Val)) |
|-------|-------|----------|---------------|---------------------|
| 1     | A     | 1        | 1             | 1                   |
| 1     | B     | 2        | 1             | 1                   |
| 1     | Total | 3        | 1             | -                   |
| 2     | A     | 3        | 3             | 1                   |
| 2     | B     | 4        | 3             | 1                   |
| 2     | Total | 7        | 3             | -                   |
| 3     | A     | 5        | 5             | 1                   |
| 3     | B     | 6        | 5             | 1                   |
| 3     | Total | 11       | 5             | -                   |
| Total | -     | 21       | -             | 1                   |

The expression using the **top** function without the **total** qualifier will evaluate to NULL in the total row, because it cannot be clearly associated with a specific column segment. However, all the partial sums will be evaluated for each column segment.

The expression using the **total** qualifier will lack values in the partial totals but will return a value in the grand total row.

**Example 3:**

Study the following straight table sorted on the field Grp:

| Two dimension straight table - sort on Grp |     |          |               |                        |
|--------------------------------------------|-----|----------|---------------|------------------------|
| Month                                      | Grp | sum(Val) | top(sum(Val)) | sum(Val)/top(sum(Val)) |
|                                            |     | 21       | -             | -                      |
| 1                                          | A   | 1        | 1             | 100%                   |
| 2                                          | A   | 3        | 1             | 300%                   |
| 3                                          | A   | 5        | 1             | 500%                   |
| 1                                          | B   | 2        | 2             | 100%                   |
| 2                                          | B   | 4        | 2             | 200%                   |
| 3                                          | B   | 6        | 2             | 300%                   |

Example table: Two dimensional straight table sorted by Grp

| Month | Grp | sum(Val) | top(sum(Val)) | sum(Val) / top(sum(Val)) |
|-------|-----|----------|---------------|--------------------------|
| -     | -   | 21       | -             | -                        |
| 1     | A   | 1        | 1             | 100%                     |
| 2     | A   | 3        | 1             | 300%                     |
| 3     | A   | 5        | 1             | 500%                     |
| 1     | B   | 2        | 2             | 100%                     |
| 2     | B   | 4        | 2             | 200%                     |
| 3     | B   | 6        | 2             | 300%                     |

We may continue by changing the inter field sort order so that the chart is sorted primarily on the field Month. The table will now look like this:

| Two dimension straight table - sort on Month |     |          |               |                        |
|----------------------------------------------|-----|----------|---------------|------------------------|
| Month                                        | Grp | sum(Val) | top(sum(Val)) | sum(Val)/top(sum(Val)) |
|                                              |     | 21       | -             | -                      |
| 1                                            | A   | 1        | 1             | 100%                   |
| 1                                            | B   | 2        | 1             | 200%                   |
| 2                                            | A   | 3        | 3             | 100%                   |
| 2                                            | B   | 4        | 3             | 133%                   |
| 3                                            | A   | 5        | 5             | 100%                   |
| 3                                            | B   | 6        | 5             | 120%                   |

Example table: Two dimensional straight table sorted by Month

| Month | Grp | sum(Val) | top(sum(Val)) | sum(Val) / top(sum(Val)) |
|-------|-----|----------|---------------|--------------------------|
| -     | -   | 21       | -             | -                        |
| 1     | A   | 1        | 1             | 100%                     |
| 1     | B   | 2        | 1             | 200%                     |

| Month | Grp | sum(Val) | top(sum(Val)) | sum(Val) / top(sum(Val)) |
|-------|-----|----------|---------------|--------------------------|
| 2     | A   | 3        | 3             | 100%                     |
| 2     | B   | 4        | 3             | 133%                     |
| 3     | A   | 5        | 5             | 100%                     |
| 3     | B   | 6        | 5             | 120%                     |

### Above Function Examples

These examples are made with the **above** function, but may be applied in a similar manner to the **below**, **before** and **after** functions. However, note that the **before** and **after** functions are relevant only to pivot tables.

#### Example 4:

Study the straight table below, depicting the use of the **above** function in a one-dimensional table:

| Month | sum(Val) | above(sum(Val)) | sum(Val)/above(sum(Val)) |
|-------|----------|-----------------|--------------------------|
|       | 21       | -               | -                        |
| 1     | 3        | -               | -                        |
| 2     | 7        | 3               | 233%                     |
| 3     | 11       | 7               | 157%                     |

Example table: One dimensional straight table with Above function

| Month | sum(Val) | above(sum(Val)) | sum(Val) / above(sum(Val)) |
|-------|----------|-----------------|----------------------------|
| -     | 21       | -               | -                          |
| 1     | 3        | -               | -                          |
| 2     | 7        | 3               | 233%                       |
| 3     | 11       | 7               | 157%                       |

The third column shows the expression **sum(Val)** evaluated one row above the current row, which can be confirmed by comparing with the values for **sum(val)** in the second column. The **above** function returns NULL on the first row, as there is no row above on which to evaluate the expression. The **above** function always returns NULL on all total rows.

The fourth column demonstrates the most typical use of this function, i.e. to calculate the difference between e.g. different time periods.

#### Example 5:

Study the two-dimensional pivot table below:

| Grp   | Month | sum(Val) | above(sum(Val)) | above(total sum(Val)) |
|-------|-------|----------|-----------------|-----------------------|
| A     | 1     | 1        | -               | -                     |
|       | 2     | 3        | 1               | 1                     |
|       | 3     | 5        | 3               | 3                     |
|       | Total | 9        | -               | -                     |
| B     | 1     | 2        | -               | 5                     |
|       | 2     | 4        | 2               | 2                     |
|       | 3     | 6        | 4               | 4                     |
|       | Total | 12       | -               | -                     |
| Total |       | 21       | -               | -                     |

Example table: Two dimensional pivot table with total qualifier

| Grp   | Month | sum(Val) | above(sum(Val)) | above(total sum(Val)) |
|-------|-------|----------|-----------------|-----------------------|
| A     | 1     | 1        | -               | -                     |
| A     | 2     | 3        | 1               | 1                     |
| A     | 3     | 5        | 3               | 3                     |
| A     | Total | 9        | -               | -                     |
| B     | 1     | 2        | -               | 5                     |
| B     | 2     | 4        | 2               | 2                     |
| B     | 3     | 6        | 4               | 4                     |
| B     | Total | 12       | -               | -                     |
| Total | -     | 21       | -               | -                     |

The **above** function without the **total** qualifier (third column) will only act within each sort group. A NULL value will be returned on the top row of each column segment.

When a **total** qualifier is added (fourth column), the entire column will be regarded as one column segment. Only the top row will return NULL. All total rows are disregarded and return NULL.

### RowNo and NoOfRows Function Examples

This example is made with the **RowNo** and **NoOfRows** functions, but may be applied in a similar manner to the **ColumnNo** and **NoOfColumns** functions. However, note that the **ColumnNo** and **NoOfColumns** functions are relevant only to pivot tables.

#### Example 6:

Study the two-dimensional pivot table below:

| rowno() and noofrows() |       |         |              |            |                 |
|------------------------|-------|---------|--------------|------------|-----------------|
| Month                  | Grp   | rowno() | rowno(total) | noofrows() | noofrows(total) |
| 1                      | A     | 1       | 1            | 2          | 6               |
|                        | B     | 2       | 2            | 2          | 6               |
|                        | Total | 0       | -            | 2          | -               |
| 2                      | A     | 1       | 3            | 2          | 6               |
|                        | B     | 2       | 4            | 2          | 6               |
|                        | Total | 0       | -            | 2          | -               |
| 3                      | A     | 1       | 5            | 2          | 6               |
|                        | B     | 2       | 6            | 2          | 6               |
|                        | Total | 0       | -            | 2          | -               |
| Total                  |       | -       | 0            | -          | 6               |

Example table: RowNo and NoOfRows functions

| Month | Grp   | RowNo() | RowNo(total) | NoOfRows() | NoOfRows(total) |
|-------|-------|---------|--------------|------------|-----------------|
| 1     | A     | 1       | 1            | 2          | 6               |
| 1     | B     | 2       | 2            | 2          | 6               |
| 1     | Total | 0       | -            | 2          | -               |
| 2     | A     | 1       | 3            | 2          | 6               |
| 2     | B     | 2       | 4            | 2          | 6               |
| 2     | Total | 0       | -            | 2          | -               |
| 3     | A     | 1       | 5            | 2          | 6               |
| 3     | B     | 2       | 6            | 2          | 6               |
| 3     | Total | 0       | -            | 2          | -               |
| Total | -     | -       | 0            | -          | 6               |

- **Column 3** The **RowNo** function will return the row number within each sort group column segment. In subtotal rows, the row number 0 will be returned, because these totals clearly belong to a specific column segment. NULL will be returned in the grand total row.
- **Column 4** With the total qualifier, the **RowNo** function will return the row number within the entire column. In subtotal rows a NULL value will be returned. In the grand total row 0 will be returned.
- **Column 5** The **NoOfRows** function will return the number of data rows within each sort group column segment. In subtotal rows, the same number will be returned as in data rows. NULL will be returned in the grand total row.
- **Column 6** With the total qualifier, the **NoOfRows** function will return the number of data rows within the entire column, which is the same as what will be returned in the grand total row. In subtotal rows NULL will be returned.

### Calculated Formulas

In the property dialogs of the QlikView sheets and sheet objects, there are a number of properties allowing fixed text labels or fixed numbers. These are typically used as labels, window titles, chart titles and in some cases as fixed numeric limits.

For many of the property entries mentioned above, it is possible to enter a calculated expression rather than a constant text or number. This feature is called calculated formula. Wherever a calculated formula can be used, this is indicated on the relevant place in this documentation.

### Entering a Calculated Formula

Calculated formulas are entered according to the following syntax:

```
= expression
```

For the syntax of allowed expressions, see the section below.

The equal sign in the first position of the entry indicates that the remainder should be interpreted as an expression. QlikView will try to evaluate the expression. If this is not possible, e.g. because of incorrect syntax, the entire label including the equal sign will be displayed.

Calculated formulas can also be generated in the **Edit Expression** dialog which opens when clicking on the ... button beside the edit box.

### Error Messages

If a calculated formula cannot be correctly evaluated by QlikView, the formula itself will be returned, followed by two slashes and an error message.

#### Example:

```
= mode(x) //out of object memory
```

Each calculated formula requires a certain amount of memory. In order not to use excessive memory, a limit on the allowed memory allocation for each calculated label has been put in to the program. If you enter a too complex expression, QlikView will return the expression followed by the error message “// out of object memory”.

### Expression syntax for calculated formulas

The syntax for **expression** in calculated labels is virtually the same as for chart expressions, with a few exceptions:

- With no dimensions to iterate over, the chart aggregation functions will essentially behave as if used in chart expressions with the **total** qualifier in front of all field names. The **total** qualifier is thus optional and has no special meaning in calculated formulas. The **set** definitions work just as in chart expressions, i.e. they cause aggregations over a selection different than the current one.
- In a calculated formula, field names may optionally be used without an enclosing aggregation function. In this case **only** will be used as an aggregation function.

### Example:

= Currency

is equal to

= only(Currency)

## 9.6 Operators

This section describes the operators that can be used in QlikView. There are two types of operators:

- Unary operators (take only one operand)
- Binary operators (take two operands)

Most operators are binary.

The following operators can be defined:

- Bit operators
- Logical operators
- Numeric operators
- Relational operators
- String operators

### Bit operators

All bit operators convert (truncate) the operands to signed integers (32 bit) and return the result in the same way. All operations are performed bit by bit. If an operand cannot be interpreted as a number, the operation will return NULL.

Bit operators

| Bit operator | Operator name | Operator function                                                                                                                                  |
|--------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| bitnot       | Bit inverse   | Unary operator. The operation returns the logical inverse of the operand performed bit by bit.<br><br><b>Example:</b><br><br>bitnot 17 returns -18 |
| bitand       | Bit and       | The operation returns the logical AND of the operands performed bit by bit.<br><br><b>Example:</b><br><br>17 bitand 7 returns 1                    |

| Bit operator | Operator name    | Operator function                                                                                                                                                  |
|--------------|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bitor        | Bit or           | The operation returns the logical OR of the operands performed bit by bit.<br><br><b>Example:</b><br><br>17 bitor 7 returns 23                                     |
| bitxor       | Bit exclusive or | The operation returns the logical exclusive or of the operands performed bit by bit.<br><br><b>Example:</b><br><br>17 bitxor 7 returns 22                          |
| >>           | Bit right shift  | The operation returns the first operand shifted to the right. The number of steps is defined in the second operand.<br><br><b>Example:</b><br><br>8 >> 2 returns 2 |
| <<           | Bit left shift   | The operation returns the first operand shifted to the left. The number of steps is defined in the second operand.<br><br><b>Example:</b><br><br>8 << 2 returns 32 |

### Logical operators

All logical operators interpret the operands logically and return True (-1) or False (0) as result.

Logical operators

| Logical operator | Operator function                                                                                                                                                                       |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| not              | Logical inverse. One of the few unary operators. The operation returns the logical inverse of the operand.                                                                              |
| and              | Logical and. The operation returns the logical and of the operands.                                                                                                                     |
| or               | Logical or. The operation returns the logical or of the operands.                                                                                                                       |
| Xor              | Logical exclusive or. The operation returns the logical exclusive or of the operands. I.e. like logical or, but with the difference that the result is False if both operands are True. |

### Numeric operators

All numeric operators use the numeric values of the operands and return a numeric value as result.

### Numeric operators

| Numeric operator | Operator function                                                                                                                                                                      |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| +                | Sign for positive number (unary operator) or arithmetic addition. The binary operation returns the sum of the two operands.                                                            |
| -                | Sign for negative number (unary operator) or arithmetic subtraction. The unary operation returns the operand multiplied by -1, and the binary the difference between the two operands. |
| *                | Arithmetic multiplication. The operation returns the product of the two operands.                                                                                                      |
| /                | Arithmetic division. The operation returns the ratio between the two operands.                                                                                                         |

### Relational operators

All relational operators compare the values of the operands and return True (-1) or False (0) as the result. All relational operators are binary.

### Relational operators

| Relational operator | Operator name         | Operator function                                                                                                                                          |
|---------------------|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <                   | Less than             | A numeric comparison is made if both operands can be interpreted numerically. The operation returns the logical value of the evaluation of the comparison. |
| <=                  | Less than or equal    | A numeric comparison is made if both operands can be interpreted numerically. The operation returns the logical value of the evaluation of the comparison. |
| >                   | Greater than          | A numeric comparison is made if both operands can be interpreted numerically. The operation returns the logical value of the evaluation of the comparison. |
| >=                  | Greater than or equal | A numeric comparison is made if both operands can be interpreted numerically. The operation returns the logical value of the evaluation of the comparison. |
| =                   | Equals                | A numeric comparison is made if both operands can be interpreted numerically. The operation returns the logical value of the evaluation of the comparison. |
| <>                  | Not equivalent to     | A numeric comparison is made if both operands can be interpreted numerically. The operation returns the logical value of the evaluation of the comparison. |

| Relational operator | Operator name | Operator function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>precedes</b>     |               | <p>Unlike the &lt; operator no attempt is made to make a numeric interpretation of the argument values before the comparison. The operation returns true if the value to the left of the operator has a text representation which, in string comparison, comes before the text representation of the value on the right.</p> <p><b>Example:</b></p> <p>'1 ' precedes ' 2' returns FALSE</p> <p>whilst</p> <p>' 1' precedes ' 2' returns TRUE</p> <p>as the ASCII value of a space (' ') is of less value than the ASCII value of a number.</p> <p>Compare this to:</p> <p>'1 ' &lt; ' 2' returns TRUE</p> <p>and</p> <p>' 1' &lt; ' 2' returns TRUE</p> |
| <b>follows</b>      |               | <p>Unlike the &gt; operator no attempt is made to make a numeric interpretation of the argument values before the comparison. The operation returns true if the value to the left of the operator has a text representation which, in string comparison, comes after the text representation of the value on the right.</p> <p><b>Example:</b></p> <p>' 2' follows '1' returns FALSE</p> <p>whilst</p> <p>'2' follows ' 1' returns TRUE</p> <p>as the ASCII value of a space (' ') is of less value than the ASCII value of a number.</p> <p>Compare this to:</p> <p>' 2' &gt; ' 1' returns TRUE</p> <p>and</p> <p>' 2' &gt; '1 ' returns TRUE</p>      |

### String operators

There are two string operators. One uses the string values of the operands and return a string as result. The other one compares the operands and returns a boolean value to indicate match.

String operators

| String operator | Operator description                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| &               | String concatenation. The operation returns a text string, that consists of the two operand strings, one after another.<br><br><b>Example:</b><br>'abc' & 'xyz' returns 'abcxyz'                                                                                                                                                                                                                                                                          |
| like            | String comparison with wildcard characters. The operation returns a boolean True (-1) if the string before the operator is matched by the string after the operator. The second string may contain the wildcard characters * (any number of arbitrary characters) or ? (one arbitrary character).<br><br><b>Example:</b><br><br>'abc' like 'a*' returns True (-1)<br><br>'abcd' like 'a?c*' returns True (-1)<br><br>'abc' like 'a??bc' returns False (0) |

## 9.7 Functions in scripts and chart expressions

This section describes functions that can be used in QlikView load scripts and chart expressions to transform and aggregate data.

Many functions can be used in the same way in both load scripts and chart expressions, but there are a number of exceptions:

- Some functions can only be used in load scripts, denoted by - script function.
- Some functions can only be used in chart expressions, denoted by - chart function.
- Some functions can be used in both load scripts and chart expressions, but with differences in parameters and application. These are described in separate topics denoted by - script function or - chart function.

### Analytic connections

For both QlikView Desktop and QlikView Server, analytic connections are configured by editing the *settings.ini* file. Functions enabled by analytic connections will only be visible if you have configured the analytic connection in the *setting.ini* file and QlikView has started. See how to create an analytic connection in the Analytic connections page.

### Aggregation functions

The family of functions known as aggregation functions consists of functions that take multiple field values as their input and return a single result per group, where the grouping is defined by a chart dimension or a **group by** clause in the script statement.

Aggregation functions include **Sum()**, **Count()**, **Min()**, **Max()**, and many more.

Most aggregation functions can be used in both the data load script and chart expressions, but the syntax differs.

#### Using aggregation functions in a data load script

Aggregation functions can only be used inside **LOAD** and **SELECT** statements.

#### Using aggregation functions in chart expressions

The parameter of the aggregation function must not contain other aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

An aggregation function aggregates over the set of possible records defined by the selection. However, an alternative set of records can be defined by using a set expression in set analysis.

#### How aggregations are calculated

An aggregation loops over the records of a specific table, aggregating the records in it. For example, **Count** (<Field>) will count the number of records in the table where <Field> resides. Should you want to aggregate just the distinct field values, you need to use the **distinct** clause, such as **Count(distinct <Field>)**.

If the aggregation function contains fields from different tables, the aggregation function will loop over the records of the cross product of the tables of the constituent fields. This has a performance penalty, and for this reason such aggregations should be avoided, particularly when you have large amounts of data.

#### Aggregation of key fields

The way aggregations are calculated means that you cannot aggregate key fields because it is not clear which table should be used for the aggregation. For example, if the field <Key> links two tables, it is not clear whether **Count(<Key>)** should return the number of records from the first or the second table.

However, if you use the **distinct** clause, the aggregation is well-defined and can be calculated for a key field linked across two tables.

If you use a key field inside an aggregation function without the **distinct** clause, QlikView will return a number which may be meaningless. The solution is to either use the **distinct** clause, or use a copy of the key - a copy that resides in one table only.

For example, in the following tables, *ProductID* is the key between the tables.

*ProductID* key between *Products* and *Details* tables

*Count(ProductID)* can be counted either in the *Products* table (which has only one record per product - *ProductID* is the primary key) or it can be counted in the *Details* table (which most likely has several records per product). If you want to count the number of distinct products, you should use *Count(distinct ProductID)*. If you want to count the number of rows in a specific table, you should not use the key.

### Aggregations of key fields contained in three or more tables

The **distinct** prefix only works with key fields linking up to two tables. When grouping an aggregation over a key field that exists in three or more tables, any operation that requires frequency information for a field will return NULL. In the case of a key field linking three or more tables, a non-key copy of the field must be used instead.

### Aggr

**Aggr()** returns an array of values for the expression calculated over the stated dimension or dimensions. For example, the maximum value of sales, per customer, per region.

The **Aggr** function is used for nested aggregations, in which its first parameter (the inner aggregation) is calculated once per dimensional value. The dimensions are specified in the second parameter (and subsequent parameters).

In addition, the **Aggr** function should be enclosed in an outer aggregation function, using the array of results from the **Aggr** function as input to the aggregation in which it is nested

#### Syntax:

```
Aggr ({SetExpression} [DISTINCT] [NODISTINCT] expr, StructuredParameter{, StructuredParameter})
```

**Return data type:** dual

#### Arguments:

- *expr*: An expression consisting of an aggregation function. By default, the aggregation function will aggregate over the set of possible records defined by the selection.

- **StructuredParameter:** StructuredParameter consists of a dimension and optionally, sorting criteria in the format: (Dimension(sort-type, ordering)). The dimension is a single field and cannot be an expression. The dimension is used to determine the array of values the Aggr expression is calculated for.  
If sorting criteria are included, the array of values created by the Aggr function, calculated for the dimension, is sorted. This is important when the sort order affects the result of the expression the Aggr function is enclosed in. For details of how to use sorting criteria, see *Adding sorting criteria to the dimension in the structured parameter (page 1048)*.
- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT:** If the expression argument is preceded by the **distinct** qualifier or if no qualifier is used at all, each distinct combination of dimension values will generate only one return value. This is the normal way aggregations are made - each distinct combination of dimension values will render one line in the chart.
- **NODISTINCT:** If the expression argument is preceded by the **nodistinct** qualifier, each combination of dimension values may generate more than one return value, depending on underlying data structure. If there is only one dimension, the **aggr** function will return an array with the same number of elements as there are rows in the source data.

Basic aggregation functions, such as **Sum**, **Min**, and **Avg**, return a single numerical value whereas the **Aggr()** function can be compared to creating a temporary staged result set (a virtual table) over which another aggregation can be made. For example, by computing an average sales value by summing the sales by customer in an **Aggr()** statement and then calculating the average of the summed results: **Avg (TOTAL Aggr(Sum(Sales), Customer))**.

*Use the Aggr() function in calculated dimensions if you want to create nested chart aggregation in multiple levels.*

### Limitations:

Each dimension in an Aggr() function must be a single field, and cannot be an expression (calculated dimension).

### Adding sorting criteria to the dimension in the structured parameter

In its basic form, the argument StructuredParameter in the Aggr function syntax is a single dimension. The expression: **Aggr(Sum(Sales, Month))** finds the total value of sales for each month. However, when enclosed in another aggregation function, there can be unexpected results unless sorting criteria are used. This is because some dimensions can be sorted numerically or alphabetically, and so on.

In the StructuredParameter argument in the Aggr function, you can specify sorting criteria on the dimension in your expression. This way, you impose a sort order on the virtual table that is produced by the Aggr function.

The argument StructuredParameter has the following syntax:

---

## 9 Script syntax and chart functions

---

```
(FieldName, (Sort-type, Ordering))
```

Structured parameters can be nested:

```
(FieldName, (FieldName2, (Sort-type, Ordering)))
```

Sort-type can be: NUMERIC, TEXT, FREQUENCY, or LOAD\_ORDER.

The ordering types associated with each Sort-type are as follows:

Sort ordering types

| Sort type  | Available ordering types                    |
|------------|---------------------------------------------|
| NUMERIC    | ASCENDING, DESCENDING, or REVERSE           |
| TEXT       | ASCENDING, A2Z, DESCENDING, REVERSE, or Z2A |
| FREQUENCY  | DESCENDING, REVERSE, or ASCENDING           |
| LOAD_ORDER | ASCENDING, ORIGINAL, DESCENDING, or REVERSE |

The ordering types REVERSE and DESCENDING are equivalent.

For Sort-type TEXT, the ordering types ASCENDING and A2Z are equivalent, and DESCENDING, REVERSE, and Z2A are equivalent.

For Sort-type LOAD\_ORDER, the ordering types ASCENDING and ORIGINAL are equivalent.

### Examples

#### Example 1:

```
Avg(Aggr(Sum(UnitSales*UnitPrice), Customer))
```

The expression `Aggr(Sum(UnitSales*UnitPrice), Customer)` finds the total value of sales by **Customer**, and returns an array of values: 295, 715, and 120 for the three **Customer** values.

Effectively, we have built a temporary list of values without having to create an explicit table or column containing those values. These values are used as input to the **Avg()** function to find the average value of sales, 376.6667. (You must have **Totals** selected under **Presentation** in the properties panel.)

#### Example 2:

```
Aggr(NODISTINCT Max(UnitPrice), Customer)
```

An array of values: 16, 16, 16, 25, 25, 25, 19, and 19. The **nodistinct** qualifier means that the array contains one element for each row in the source data: each is the maximum **UnitPrice** for each **Customer** and **Product**.

#### Example 3:

```
max(aggr(sum(Customers)-above(Sum(Customers)), (MonthYear, (NUMERIC, ASCENDING))))
```

Using sorting criteria in the structuredParameter argument in the expression: `max(aggr(sum(Customers)-above(Sum(Customers)), (MonthYear, (NUMERIC, ASCENDING))))`

Without sorting criteria the result of the expression `max(aggr(sum(Customers)-above(Sum(Customers)), (MonthYear)))` depends on how the dimension MonthYear is sorted. We might not get the result we want. By adding values for sort type and ordering type to the dimension, we give sorting criteria to the structured parameter: `(MonthYear, (NUMERIC, ASCENDING))`, where the sort type NUMERIC and ordering ASCENDING determine that MonthYear is sorted in ascending numerical order.

Here, we are looking to find the greatest increase in number of customers, month-on-month. This could be used in a KPI visualization, for example.

The Aggr part of the expression compares the total number of customers in one month (given by MonthYear) to the total number in the previous month. Because we use sorting criteria with the dimension: `(MonthYear,(NUMERIC, ASCENDING))`, we are sure that Aggr compares the numbers of customers in consecutive months in the virtual table by sorting the months in ascending numerical order, and not in ascending alphabetical order.

### Data used in examples:

Create a table with **Customer**, **Product**, **UnitPrice**, and **UnitSales** as dimensions. Add the expression to the table, as a measure.

```
ProductData:
LOAD * inline [
Customer|Product|UnitsSales|UnitPrice
Astrida|AA|4|16
Astrida|AA|10|15
Astrida|BB|9|9
Betacab|BB|5|10
Betacab|CC|2|20
Betacab|DD|25|25
Canutility|AA|8|15
Canutility|CC||19
] (delimiter is '|');
```

## Basic aggregation functions

### Basic aggregation functions overview

Basic aggregation functions are a group of the most common aggregation functions.

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

### Basic aggregation functions in the load script

#### FirstSortedValue

The sorted values are iterated over a number of records, as defined by a **group by** clause, or aggregated across the full data set if no **group by** clause is defined.

```
FirstSortedValue ([distinct] expression , sort-weight [, n])
```

### Max

**Max()** finds the highest numeric value of the aggregated data in the expression, as defined by a **group by** clause. By specifying a **rank** n, the nth highest value can be found.

```
Max (expression[, rank])
```

### Min

**Min()** returns the lowest numeric value of the aggregated data in the expression, as defined by a **group by** clause. By specifying a **rank** n, the nth lowest value can be found.

```
Min (expression[, rank])
```

### Mode

**Mode()** returns the most commonly-occurring value, the mode value, of the aggregated data in the expression, as defined by a **group by** clause. The **Mode()** function can return numeric values as well as text values.

```
Mode (expression)
```

### Only

**Only()** returns a value if there is one and only one possible result from the aggregated data. If the records within each grouped result as defined by the group by clause contains only one value, then that value is returned. Otherwise NULL is returned

```
Only (expression)
```

### Sum

**Sum()** calculates the total of the values aggregated in the expression, as defined by a **group by** clause.

```
Sum ([distinct]expression)
```

### Basic aggregation functions in chart expressions

Chart aggregation functions can only be used on fields in chart expressions. The argument expression of one aggregation function must not contain another aggregation function.

#### FirstSortedValue

**FirstSortedValue()** returns the value from the expression specified in **value** that corresponds to the result of sorting the **sort\_weight** argument, taking into account **rank**, if specified. If more than one resulting value shares the same **sort\_weight** for the specified **rank**, the function returns **NULL**.

```
FirstSortedValue ([{SetExpression}] [DISTINCT] [TOTAL [<fld {,fld}>]] value,
sort_weight [,rank])
```

#### Max

**Max()** finds the highest value of the aggregated data. By specifying a **rank** n, the nth highest value can be found.

```
MaxMax() finds the highest value of the aggregated data. By specifying a rank
n, the nth highest value can be found. You might also want to look at
FirstSortedValue and rangemax, which have similar functionality to the Max
function. Max([SetExpression] [DISTINCT] [TOTAL [<fld {,fld}>]] expr
[,rank]) numeric expr: The expression or field containing the data to be
```

measured.rank: The default value of rank is 1, which corresponds to the highest value. By specifying rank as 2, the second highest value is returned. If rank is 3, the third highest value is returned, and so on.

**SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.

**TOTAL:** If the word TOTAL occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The TOTAL qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

**Examples and results**

| Example                                                                                                        | Result                                                                                                                                                                                                                                                                                           |
|----------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Max(UnitSales)                                                                                                 | 10, because this is the highest value in UnitSales.                                                                                                                                                                                                                                              |
| The value of an order is calculated from the number of units sold in (UnitSales) multiplied by the unit price. |                                                                                                                                                                                                                                                                                                  |
| Max (UnitSales*UnitPrice)                                                                                      | 150, because this is the highest value of the result of calculating all possible values of (UnitSales)*(UnitPrice).                                                                                                                                                                              |
| Max(UnitSales, 2)                                                                                              | 9, which is the second highest value.                                                                                                                                                                                                                                                            |
| Max(TOTAL UnitSales)                                                                                           | 10, because the TOTAL qualifier means the highest possible value is found, disregarding the chart dimensions. For a chart with Customer as dimension, the TOTAL qualifier will ensure the maximum value across the full dataset is returned, instead of the maximum UnitSales for each customer. |
| Make the selection Customer B.                                                                                 |                                                                                                                                                                                                                                                                                                  |
| Max({1} TOTAL UnitSales)                                                                                       | 10, independent of the selection made, because the Set Analysis expression {1} defines the set of records to be evaluated as ALL, no matter what selection is made.                                                                                                                              |

**Min** form Customer Product UnitSales UnitPrice  
AstridaAA416AstridaAA1015AstridaBB99BetacabBB510BetacabCC220BetacabDD-25CanutilityAA815CanutilityCC-19

```
Min([SetExpression] [DISTINCT] [TOTAL [<fld {,fld}>]] expr [,rank])
```

Min

**Min()** finds the lowest numeric value of the aggregated data. By specifying a **rank** n, the nth lowest value can be found.

```
Min([SetExpression] [DISTINCT] [TOTAL [<fld {,fld}>]] expr [,rank])
```

Mode

**Mode()** finds the most commonly-occurring value, the mode value, in the aggregated data. The **Mode()** function can process text values as well as numeric values.

```
Mode - chart function([SetExpression] [TOTAL [<fld {,fld}>]] expr)
```

### Only

**Only()** returns a value if there is one and only one possible result from the aggregated data. For example, searching for the only product where the unit price =9 will return NULL if more than one product has a unit price of 9.

```
Only ([{SetExpression}] [DISTINCT] [TOTAL [<fld {,fld}>]] expr)
```

### Sum

**Sum()** calculates the total of the values given by the expression or field across the aggregated data.

```
Sum - chart function([{SetExpression}] [DISTINCT] [TOTAL [<fld {,fld}>]]
expr)
```

### FirstSortedValue

**FirstSortedValue()** returns the value from the expression specified in **value** that corresponds to the result of sorting the **sort\_weight** argument, taking into account **rank**, if specified. If more than one resulting value shares the same **sort\_weight** for the specified **rank**, the function returns **NULL**.

The sorted values are iterated over a number of records, as defined by a **group by** clause, or aggregated across the full data set if no **group by** clause is defined.

#### Syntax:

```
FirstSortedValue ([distinct] value, sort-weight [, rank])
```

**Return data type:** dual

#### Arguments:

FirstSortedValue arguments

| Argument                  | Description                                                                                                                                                                                                                                                                                                         |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value<br>Expression       | The function finds the value of the expression <b>value</b> that corresponds to the result of sorting <b>sort_weight</b> .                                                                                                                                                                                          |
| sort-weight<br>Expression | The expression containing the data to be sorted. The first (lowest) value of <b>sort_weight</b> is found, from which the corresponding value of the <b>value</b> expression is determined. If you place a minus sign in front of <b>sort_weight</b> , the function returns the last (highest) sorted value instead. |
| rank<br>Expression        | By stating a <b>rank</b> "n" larger than 1, you get the nth sorted value.                                                                                                                                                                                                                                           |
| distinct                  | If the word <b>DISTINCT</b> occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.                                                                                                                                                               |

#### Examples and results:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in our document to see the result.

### Example 1:

Temp:

```
LOAD * inline [
Customer|Product|OrderNumber|UnitSales|CustomerID
Astrida|AA|1|10|1
Astrida|AA|7|18|1
Astrida|BB|4|9|1
Astrida|CC|6|2|1
Betacab|AA|5|4|2
Betacab|BB|2|5|2
Betacab|DD|12|25|2
Canutility|AA|3|8|3
Canutility|CC|13|19|3
Divadip|AA|9|16|4
Divadip|AA|10|16|4
Divadip|DD|11|10|4
] (delimiter is '|');
```

FirstSortedValue:

```
LOAD Customer,FirstSortedValue(Product, UnitSales) as MyProductWithSmallestOrderByCustomer
Resident Temp Group By Customer;
```

Example 1 results

| Result field (Customer) | Result value (MyProductWithSmallestOrderByCustomer) |
|-------------------------|-----------------------------------------------------|
| Astrida                 | CC                                                  |
| Betacab                 | AA                                                  |
| Canutility              | AA                                                  |
| Divadip                 | DD                                                  |

The function sorts UnitSales from smallest to largest, looking for the value of Customer with the smallest value of UnitSales, the smallest order.

Because CC corresponds to the smallest order (value of UnitSales=2) for customer Astrida. AA corresponds to the smallest order (4) for customer Betacab, AA corresponds to the smallest order (8) for customer Canutility, and DD corresponds to the smallest order (10) for customer Divadip.

### Example 2:

Given that the **Temp** table is loaded as in the previous example:

```
LOAD Customer,FirstSortedValue(Product, -UnitSales) as MyProductWithLargestOrderByCustomer
Resident Temp Group By Customer;
```

Example 2 results

| Result field (Customer) | Result value (MyProductWithLargestOrderByCustomer) |
|-------------------------|----------------------------------------------------|
| Astrida                 | AA                                                 |
| Betacab                 | DD                                                 |
| Canutility              | CC                                                 |
| Divadip                 | -                                                  |

A minus sign precedes the `sort_weight` argument, so the function sorts the largest first.

Because AA corresponds to the largest order (value of `UnitSales`:18) for customer Astrida, DD corresponds to the largest order (12) for customer Betacab, and CC corresponds to the largest order (13) for customer Canutility. There are two identical values for the largest order (16) for customer Divadip, therefore this produces a null result.

### Example 3:

Given that the **Temp** table is loaded as in the previous example:

```
LOAD Customer,FirstSortedValue(distinct Product, -UnitSales) as
MyProductWithSmallestOrderByCustomer Resident Temp Group By Customer;
```

Example 3 results

| Result field (Customer) | Result value (MyProductWithLargestOrderByCustomer) |
|-------------------------|----------------------------------------------------|
| Astrida                 | AA                                                 |
| Betacab                 | DD                                                 |
| Canutility              | CC                                                 |
| Divadip                 | AA                                                 |

This is the same as the previous example, except the `distinct` qualifier is used. This causes the duplicate result for Divadip to be disregarded, allowing a non-null value to be returned.

### FirstSortedValue

**FirstSortedValue()** returns the value from the expression specified in **value** that corresponds to the result of sorting the **sort\_weight** argument, taking into account **rank**, if specified. If more than one resulting value shares the same **sort\_weight** for the specified **rank**, the function returns **NULL**.

### Syntax:

```
FirstSortedValue([SetExpression] [DISTINCT] [TOTAL [<fld {,fld}>]] value,
sort_weight [,rank])
```

**Return data type:** dual

**Arguments:**

- **value:** Output field. The function finds the value of the expression **value** that corresponds to the result of sorting **sort\_weight**.
- **sort\_weight:** Input field. The expression containing the data to be sorted. The first (lowest) value of **sort\_weight** is found, from which the corresponding value of the **value** expression is determined. If you place a minus sign in front of **sort\_weight**, the function returns the last (highest) sorted value instead.
- **rank:** By stating a **rank** "n" larger than 1, you get the nth sorted value.
- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT:** If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

**Examples:**

Examples and results

| Example                                                | Result                                                                                                                                                                                                       |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| firstsortedvalue (Product, UnitPrice)                  | BB, which is the Productwith the lowest unitPrice(9).                                                                                                                                                        |
| firstsortedvalue (Product, UnitPrice, 2)               | BB, which is the Productwith the second-lowest unitPrice(10).                                                                                                                                                |
| firstsortedvalue (Customer, - UnitPrice, 2)            | Betacab, which is the Customerwith the Product that has second-highest UnitPrice(20).                                                                                                                        |
| firstsortedvalue (Customer, UnitPrice, 3)              | NULL, because there are two values of Customer (Astrida and Canutility) with the samerank (third-lowest) unitPrice(15).<br><br>Use the distinct qualifier to make sure unexpected null results do not occur. |
| firstsortedvalue (Customer, - UnitPrice*UnitsSales, 2) | Canutility, which is the Customer with the second-highest sales order value unitPrice multiplied by unitsales (120).                                                                                         |

**Data used in examples:**

```
ProductData:
LOAD * inline [
Customer|Product|UnitsSales|UnitPrice
```

```
Astrida|AA|4|16
Astrida|AA|10|15
Astrida|BB|9|9
Betacab|BB|5|10
Betacab|CC|2|20
Betacab|DD||25
Canutility|AA|8|15
Canutility|CC||19
] (delimiter is '|');
```

Example data in table form

| Customer   | Product | UnitSales | UnitPrice |
|------------|---------|-----------|-----------|
| Astrida    | AA      | 4         | 16        |
| Astrida    | AA      | 10        | 15        |
| Astrida    | BB      | 9         | 9         |
| Betacab    | BB      | 5         | 10        |
| Betacab    | CC      | 2         | 20        |
| Betacab    | DD      | -         | 25        |
| Canutility | AA      | 8         | 15        |
| Canutility | CC      | -         | 19        |

### Max

**Max()** finds the highest numeric value of the aggregated data in the expression, as defined by a **group by** clause. By specifying a **rank** n, the nth highest value can be found.

#### Syntax:

```
Max (expr [, rank])
```

**Return data type:** numeric

#### Arguments:

Max arguments

| Argument           | Description                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| expr               | The expression or field containing the data to be measured.                                                                                                                                                               |
| rank<br>Expression | The default value of <b>rank</b> is 1, which corresponds to the highest value. By specifying <b>rank</b> as 2, the second highest value is returned. If <b>rank</b> is 3, the third highest value is returned, and so on. |

#### Examples and results:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in our document to see the result.

### Example 1:

```
Temp:
LOAD * inline [
Customer|Product|OrderNumber|UnitSales|CustomerID
Astrida|AA|1|10|1
Astrida|AA|7|18|1
Astrida|BB|4|9|1
Astrida|CC|6|2|1
Betacab|AA|5|4|2
Betacab|BB|2|5|2
Betacab|DD
Canutility|DD|3|8
Canutility|CC
] (delimiter is '|');
```

```
Max:
LOAD Customer, Max(UnitSales) as MyMax Resident Temp Group By Customer;
```

Example 1 results

| Result field (Customer) | Result value (MyMax) |
|-------------------------|----------------------|
| Astrida                 | 18                   |
| Betacab                 | 5                    |
| Canutility              | 8                    |

### Example 2:

Given that the **Temp** table is loaded as in the previous example:

```
LOAD Customer, Max(UnitSales,2) as MyMaxRank2 Resident Temp Group By Customer;
```

Example 2 results

| Result field (Customer) | Result value (MyMaxRank2) |
|-------------------------|---------------------------|
| Astrida                 | 10                        |
| Betacab                 | 4                         |
| Canutility              | -                         |

### Max

**Max()** finds the highest value of the aggregated data. By specifying a **rank n**, the nth highest value can be found.

You might also want to look at **FirstSortedValue** and **rangemax**, which have similar functionality to the **Max** function.

### Syntax:

```
Max ([{SetExpression}] [DISTINCT] [TOTAL [<fld {,fld}>]] expr [,rank])
```

**Return data type:** numeric

**Arguments:**

- `expr`: The expression or field containing the data to be measured.
- `rank`: The default value of **rank** is 1, which corresponds to the highest value. By specifying **rank** as 2, the second highest value is returned. If **rank** is 3, the third highest value is returned, and so on.
- `SetExpression`: By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **TOTAL**: If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets `<fld>`. These field names should be a subset of the chart dimension variables.

**Examples:**

| Example                                                                                                                                                                      | Result                                                                                                                                                                                                                                                                                                                                   |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>Max(UnitsSales)</code>                                                                                                                                                 | 10, because this is the highest value in <code>unitsales</code> .                                                                                                                                                                                                                                                                        |
| The value of an order is calculated from the number of units sold in ( <code>UnitsSales</code> ) multiplied by the unit price.<br><br><code>Max(UnitsSales*UnitPrice)</code> | 150, because this is the highest value of the result of calculating all possible values of <code>(UnitsSales)*(UnitPrice)</code> .                                                                                                                                                                                                       |
| <code>Max(UnitsSales, 2)</code>                                                                                                                                              | 9, which is the second highest value.                                                                                                                                                                                                                                                                                                    |
| <code>Max(TOTAL UnitsSales)</code>                                                                                                                                           | 10, because the <b>TOTAL</b> qualifier means the highest possible value is found, disregarding the chart dimensions. For a chart with <code>Customer</code> as dimension, the <b>TOTAL</b> qualifier will ensure the maximum value across the full dataset is returned, instead of the maximum <code>UnitSales</code> for each customer. |
| Make the selection <code>Customer B</code> .<br><br><code>Max({1} TOTAL UnitsSales)</code>                                                                                   | 10, independent of the selection made, because the Set Analysis expression <code>{1}</code> defines the set of records to be evaluated as <b>ALL</b> , no matter what selection is made.                                                                                                                                                 |

**Data used in examples:**

```
ProductData:
LOAD * inline [
Customer|Product|UnitsSales|UnitPrice
```

```
Astrida|AA|4|16
Astrida|AA|10|15
Astrida|BB|9|9
Betacab|BB|5|10
Betacab|CC|2|20
Betacab|DD||25
Canutility|AA|8|15
Canutility|CC||19
] (delimiter is '|');
```

Example data in table form

| Customer   | Product | UnitSales | UnitPrice |
|------------|---------|-----------|-----------|
| Astrida    | AA      | 4         | 16        |
| Astrida    | AA      | 10        | 15        |
| Astrida    | BB      | 9         | 9         |
| Betacab    | BB      | 5         | 10        |
| Betacab    | CC      | 2         | 20        |
| Betacab    | DD      | -         | 25        |
| Canutility | AA      | 8         | 15        |
| Canutility | CC      | -         | 19        |

### Min

**Min()** returns the lowest numeric value of the aggregated data in the expression, as defined by a **group by** clause. By specifying a **rank** n, the nth lowest value can be found.

#### Syntax:

```
Min (expr [, rank])
```

**Return data type:** numeric

#### Arguments:

| Argument           | Description                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| expr               | The expression or field containing the data to be measured.                                                                                                                                                            |
| rank<br>Expression | The default value of <b>rank</b> is 1, which corresponds to the lowest value. By specifying <b>rank</b> as 2, the second lowest value is returned. If <b>rank</b> is 3, the third lowest value is returned, and so on. |

#### Examples and results:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in our document to see the result.

### Example 1:

```
Temp:
LOAD * inline [
Customer|Product|OrderNumber|UnitsSales|CustomerID
Astrida|AA|1|10|1
Astrida|AA|7|18|1
Astrida|BB|4|9|1
Astrida|CC|6|2|1
Betacab|AA|5|4|2
Betacab|BB|2|5|2
Betacab|DD
Canutility|DD|3|8
Canutility|CC
] (delimiter is '|');
```

```
Min:
LOAD Customer, Min(UnitsSales) as MyMin Resident Temp Group By Customer;
Example 1 results
```

| Result field (Customer) | Result value (MyMin) |
|-------------------------|----------------------|
| Astrida                 | 2                    |
| Betacab                 | 4                    |
| Canutility              | 8                    |

### Example 2:

Given that the **Temp** table is loaded as in the previous example:

```
LOAD Customer, Min(UnitsSales,2) as MyMinRank2 Resident Temp Group By Customer;
Example 2 results
```

| Result field (Customer) | Result value (MyMinRank2) |
|-------------------------|---------------------------|
| Astrida                 | 9                         |
| Betacab                 | 5                         |
| Canutility              | -                         |

### Min

**Min()** finds the lowest numeric value of the aggregated data. By specifying a **rank** n, the nth lowest value can be found.

You might also want to look at **FirstSortedValue** and **rangemin**, which have similar functionality to the **Min** function.

### Syntax:

```
Min ([{SetExpression}] [TOTAL [<fld {,fld}>]] expr [,rank])
```

**Return data type:** numeric

### Arguments:

- **expr:** The expression or field containing the data to be measured.
- **rank:** The default value of **rank** is 1, which corresponds to the highest value. By specifying **rank** as 2, the second highest value is returned. If **rank** is 3, the third highest value is returned, and so on.
- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Examples:

*The Min() function must return a non-NULL value from the array of values given by the expression, if there is one. So in the examples, because there are NULL values in the data, the function returns the first non-NULL value evaluated from the expression.*

#### Examples and results

| Example                                                                                                                                              | Result                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Min(UnitsSales)                                                                                                                                      | 2, because this is the lowest non-NULL value in unitsales.                                                                                                                                                                                                                                     |
| The value of an order is calculated from the number of units sold in (UnitsSales) multiplied by the unit price.<br><br>Min<br>(UnitsSales*UnitPrice) | 40, because this is the lowest non-NULL value result of calculating all possible values of (UnitsSales)*(UnitPrice).                                                                                                                                                                           |
| Min(UnitsSales, 2)                                                                                                                                   | 4, which is the second lowest value (after the NULL values).                                                                                                                                                                                                                                   |
| Min(TOTAL UnitsSales)                                                                                                                                | 2, because the TOTAL qualifier means the lowest possible value is found, disregarding the chart dimensions. For a chart with Customer as dimension, the TOTAL qualifier will ensure the minimum value across the full dataset is returned, instead of the minimum UnitSales for each customer. |
| Make the selection Customer B.<br><br>Min({1}<br>TOTAL UnitsSales)                                                                                   | 2, independent of the selection made, because the Set Analysis expression {1} defines the set of records to be evaluated as ALL, no matter what selection is made.                                                                                                                             |

### Data used in examples:

```
ProductData:
LOAD * inline [
Customer|Product|UnitsSales|UnitPrice
Astrida|AA|4|16
Astrida|AA|10|15
Astrida|BB|9|9
Betacab|BB|5|10
Betacab|CC|2|20
Betacab|DD||25
Canutility|AA|8|15
Canutility|CC||19
] (delimiter is '|');
```

Example data in table form

| Customer   | Product | UnitSales | UnitPrice |
|------------|---------|-----------|-----------|
| Astrida    | AA      | 4         | 16        |
| Astrida    | AA      | 10        | 15        |
| Astrida    | BB      | 9         | 9         |
| Betacab    | BB      | 5         | 10        |
| Betacab    | CC      | 2         | 20        |
| Betacab    | DD      | -         | 25        |
| Canutility | AA      | 8         | 15        |
| Canutility | CC      | -         | 19        |

### Mode

**Mode()** returns the most commonly-occurring value, the mode value, of the aggregated data in the expression, as defined by a **group by** clause. The **Mode()** function can return numeric values as well as text values.

### Syntax:

```
Mode (expr)
```

**Return data type:** dual

Mode arguments

| Argument | Description                                                 |
|----------|-------------------------------------------------------------|
| expr     | The expression or field containing the data to be measured. |

### Limitations:

If more than one value is equally commonly occurring, NULL is returned.

### Examples and results:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in our document to see the result.

Temp:

```
LOAD * inline [
Customer|Product|OrderNumber|UnitSales|CustomerID
Astrida|AA|1|10|1
Astrida|AA|7|18|1
Astrida|BB|4|9|1
Astrida|CC|6|2|1
Betacab|AA|5|4|2
Betacab|BB|2|5|2
Betacab|DD
Canutility|DD|3|8
Canutility|CC
] (delimiter is '|');
```

Mode:

```
LOAD Customer, Mode(Product) as MyMostOftenSoldProduct Resident Temp Group By Customer;
```

Example 1 results

| Result field (Customer) | Result value (MyMostOftenSoldProduct) |
|-------------------------|---------------------------------------|
| Astrida                 | AA                                    |
| Betacab                 | -                                     |
| Canutility              | -                                     |

### Mode - chart function

**Mode()** finds the most commonly-occurring value, the mode value, in the aggregated data. The **Mode()** function can process text values as well as numeric values.

#### Syntax:

```
Mode ([{SetExpression}] [TOTAL [<fld {,fld}>]] expr)
```

**Return data type:** dual

#### Arguments:

- **expr:** The expression or field containing the data to be measured.
- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Examples:

Examples and results

| Example                                                               | Result                                                                                                                                                              |
|-----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Mode(UnitPrice)<br>Make the selection<br>Customer A.                  | 15, because this is the most commonly-occurring value in unitsales.<br><br>Returns NULL (-). No single value occurs more often than another.                        |
| Mode(Product)<br>Make the selection<br>Customer A                     | AA, because this is the most commonly occurring value in Product.<br><br>Returns NULL (-). No single value occurs more often than another.                          |
| Mode<br>(TOTAL UnitPrice)                                             | 15, because the TOTAL qualifier means the most commonly occurring value is still 15, even disregarding the chart dimensions.                                        |
| Make the selection<br>Customer B.<br><br>Mode({1}<br>TOTAL UnitPrice) | 15, independent of the selection made, because the Set Analysis expression {1} defines the set of records to be evaluated as ALL, no matter what selection is made. |

### Data used in examples:

```

ProductData:
LOAD * inline [
Customer|Product|Unitsales|UnitPrice
Astrida|AA|4|16
Astrida|AA|10|15
Astrida|BB|9|9
Betacab|BB|5|10
Betacab|CC|2|20
Betacab|DD||25
Canutility|AA|8|15
Canutility|CC||19
] (delimiter is '|');

```

Example data in table form

| Customer   | Product | UnitSales | UnitPrice |
|------------|---------|-----------|-----------|
| Astrida    | AA      | 4         | 16        |
| Astrida    | AA      | 10        | 15        |
| Astrida    | BB      | 9         | 9         |
| Betacab    | BB      | 5         | 10        |
| Betacab    | CC      | 2         | 20        |
| Betacab    | DD      | -         | 25        |
| Canutility | AA      | 8         | 15        |
| Canutility | CC      | -         | 19        |

### Only

**Only()** returns a value if there is one and only one possible result from the aggregated data. If the records within each grouped result as defined by the group by clause contains only one value, then that value is returned. Otherwise NULL is returned

#### Syntax:

```
Only (expr)
```

**Return data type:** dual

Only arguments

| Argument | Description                                                 |
|----------|-------------------------------------------------------------|
| expr     | The expression or field containing the data to be measured. |

#### Examples and results:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in our document to see the result.

Temp:

```
LOAD * inline [
Customer|Product|OrderNumber|UnitSales|CustomerID
Astrida|AA|1|10|1
Astrida|AA|7|18|1
Astrida|BB|4|9|1
Astrida|CC|6|2|1
Betacab|AA|5|4|2
Betacab|BB|2|5|2
Betacab|DD
Canutility|DD|3|8
Canutility|CC
] (delimiter is '|');
```

only:

```
LOAD Customer, Only(CustomerID) as MyUniqIDCheck Resident Temp Group By Customer;
```

Example 1 results

| Result field (Customer) | Result value (MyUniqIDCheck)                                                           |
|-------------------------|----------------------------------------------------------------------------------------|
| Astrida                 | 1<br><br>(because only customer Astrida has complete records that include CustomerID.) |

### Only

**Only()** returns a value if there is one and only one possible result from the aggregated data. For example, searching for the only product where the unit price =9 will return NULL if more than one product has a unit price of 9.

#### Syntax:

```
Only ([{SetExpression}] [TOTAL [<fld {,fld}>]] expr)
```

**Return data type:** dual

#### Arguments:

- **expr:** The expression or field containing the data to be measured.
- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

*Use Only() when you want a NULL result if there are multiple possible values in the sample data.*

#### Examples:

##### Examples and results

| Example                            | Result                                                                                                                      |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| Only({<UnitPrice={9}>} Product)    | BB, because this is the only product that has a unit price of '9'.                                                          |
| Only({<Product={DD}>} Customer)    | Betacab, because this is the only customer selling a product called 'DD'.                                                   |
| Only({<UnitPrice={20}>} Unitsales) | The number of unitsales where unit price is 20 is 2, because there is only one value of unitsales where the unit price =20. |
| Only({<UnitPrice={15}>} Unitsales) | NULL, because there are two values of unitsales where the unit price =15.                                                   |

#### Data used in examples:

```
ProductData:
LOAD * inline [
Customer|Product|Unitsales|UnitPrice
Astrida|AA|4|16
Astrida|AA|10|15
Astrida|BB|9|9
```

```
Betacab|BB|5|10
Betacab|CC|2|20
Betacab|DD|25
Canutility|AA|8|15
Canutility|CC||19
] (delimiter is '|');
```

Example data in table form

| Customer   | Product | UnitSales | UnitPrice |
|------------|---------|-----------|-----------|
| Astrida    | AA      | 4         | 16        |
| Astrida    | AA      | 10        | 15        |
| Astrida    | BB      | 9         | 9         |
| Betacab    | BB      | 5         | 10        |
| Betacab    | CC      | 2         | 20        |
| Betacab    | DD      | -         | 25        |
| Canutility | AA      | 8         | 15        |
| Canutility | CC      | -         | 19        |

### Sum

**Sum()** calculates the total of the values aggregated in the expression, as defined by a **group by** clause.

#### Syntax:

```
sum ([distinct] expr)
```

**Return data type:** numeric

#### Arguments:

Sum arguments

| Argument | Description                                                                                   |
|----------|-----------------------------------------------------------------------------------------------|
| distinct | If the word <b>distinct</b> occurs before the expression, all duplicates will be disregarded. |
| expr     | The expression or field containing the data to be measured.                                   |

#### Examples and results:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in our document to see the result.

```
Temp:
LOAD * inline [
Customer|Product|OrderNumber|UnitSales|CustomerID
Astrida|AA|1|10|1
Astrida|AA|7|18|1
Astrida|BB|4|9|1
```

```
Astrida|CC|6|2|1
Betacab|AA|5|4|2
Betacab|BB|2|5|2
Betacab|DD
Canutility|DD|3|8
Canutility|CC
] (delimiter is '|');
```

Sum:

```
LOAD Customer, Sum(UnitSales) as MySum Resident Temp Group By Customer;
```

Example 1 results

| Result field (Customer) | Result value (MySum) |
|-------------------------|----------------------|
| Astrida                 | 39                   |
| Betacab                 | 9                    |
| Canutility              | 8                    |

### Sum - chart function

**Sum()** calculates the total of the values given by the expression or field across the aggregated data.

#### Syntax:

```
Sum ([{SetExpression}] [DISTINCT] [TOTAL [<fld {,fld}>]] expr)
```

**Return data type:** numeric

#### Arguments:

- **expr:** The expression or field containing the data to be measured.
- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT:** If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.

*Although the **DISTINCT** qualifier is supported, use it only with extreme caution because it may mislead the reader into thinking a total value is shown when some data has been omitted.*

- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Examples:

Examples and results

| Example                                                                     | Result                                                                                                                                                               |
|-----------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Sum(UnitSales)                                                              | 38. The total of the values in unitSales.                                                                                                                            |
| Sum(UnitSales*UnitPrice)                                                    | 505. The total of unitPrice multiplied by unitSales aggregated.                                                                                                      |
| Sum<br>(TOTAL UnitSales*UnitPrice)                                          | 505 for all rows in the table as well as the total, because the TOTAL qualifier means the sum is still 505, disregarding the chart dimensions.                       |
| Make the selection Customer B.<br><br>Sum({1}<br>TOTAL UnitSales*UnitPrice) | 505, independent of the selection made, because the Set Analysis expression {1} defines the set of records to be evaluated as ALL, no matter what selection is made. |

### Data used in examples:

```
ProductData:
LOAD * inline [
Customer|Product|UnitSales|UnitPrice
Astrida|AA|4|16
Astrida|AA|10|15
Astrida|BB|9|9
Betacab|BB|5|10
Betacab|CC|2|20
Betacab|DD||25
Canutility|AA|8|15
Canutility|CC||19
] (delimiter is '|');
```

Example data in table form

| Customer   | Product | UnitSales | UnitPrice |
|------------|---------|-----------|-----------|
| Astrida    | AA      | 4         | 16        |
| Astrida    | AA      | 10        | 15        |
| Astrida    | BB      | 9         | 9         |
| Betacab    | BB      | 5         | 10        |
| Betacab    | CC      | 2         | 20        |
| Betacab    | DD      | -         | 25        |
| Canutility | AA      | 8         | 15        |
| Canutility | CC      | -         | 19        |

### Counter aggregation functions

Counter aggregation functions return various types of counts of an expression over a number of records in a load script, or a number of values in a chart dimension.

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

#### Counter aggregation functions in the load script

##### Count

**Count()** returns the number of values aggregated in expression, as defined by a **group by** clause.

```
Count ([distinct] expression)
```

##### MissingCount

**MissingCount()** returns the number of missing values aggregated in the expression, as defined by a **group by** clause.

```
MissingCount ([distinct] expression)
```

##### NullCount

**NullCount()** returns the number of NULL values aggregated in the expression, as defined by a **group by** clause.

```
NullCount ([distinct] expression)
```

##### NumericCount

**NumericCount()** returns the number of numeric values found in the expression, as defined by a **group by** clause.

```
NumericCount ([distinct] expression)
```

##### TextCount

**TextCount()** returns the number of field values that are non-numeric aggregated in the expression, as defined by a **group by** clause.

```
TextCount ([distinct] expression)
```

#### Counter aggregation functions in chart expressions

The following counter aggregation functions can be used in charts:

##### Count

**Count()** is used to aggregate the number of values, text and numeric, in each chart dimension.

```
Count([[SetExpression]] [DISTINCT] [TOTAL [<fld {,fld}>]] expr)
```

##### MissingCount

**MissingCount()** is used to aggregate the number of missing values in each chart dimension. Missing values are all non-numeric values.

```
MissingCount([{SetExpression}] [DISTINCT] [TOTAL [<fld {,fld}>]] expr)
```

NullCount

**NullCount()** is used to aggregate the number of NULL values in each chart dimension.

```
NullCount([{SetExpression}] [DISTINCT] [TOTAL [<fld {,fld}>]] expr)
```

NumericCount

**NumericCount()** aggregates the number of numeric values in each chart dimension.

```
NumericCount([{SetExpression}] [DISTINCT] [TOTAL [<fld {,fld}>]] expr)
```

TextCount

**TextCount()** is used to aggregate the number of field values that are non-numeric in each chart dimension.

```
TextCount - chart function([{SetExpression}] [DISTINCT] [TOTAL [<fld {,fld}>]] expr)
```

Count

**Count()** returns the number of values aggregated in expression, as defined by a **group by** clause.

**Syntax:**

```
Count([distinct] expr)
```

**Return data type:** integer

**Arguments:**

Count arguments

| Argument | Description                                                                               |
|----------|-------------------------------------------------------------------------------------------|
| expr     | The expression or field containing the data to be measured.                               |
| distinct | If the word <b>distinct</b> occurs before the expression, all duplicates are disregarded. |

**Examples and results:**

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in our document to see the result.

### Examples and results

| Example                                                                                                                                                                                                                                                                                                                                                                                          | Result                                                                                                                                                                                                             |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <p>Given that the <b>Temp</b> table is loaded as in the previous example:</p> <pre>LOAD Count(OrderNumber) as TotalOrderNumber Resident Temp;</pre>                                                                                                                                                                                                                                              | <pre>TotalOrderNumber 10</pre>                                                                                                                                                                                     |
| <p>Given that the <b>Temp</b> table is loaded as in the first example:</p> <pre>LOAD Count(distinct OrderNumber) as TotalOrderNumber Resident Temp;</pre>                                                                                                                                                                                                                                        | <pre>TotalOrderNumber 8</pre> <p>Because there are two values of OrderNumber with the same value, 1, and one null value.</p>                                                                                       |

### Count

**Count()** is used to aggregate the number of values, text and numeric, in each chart dimension.

#### Syntax:

```
Count ([{SetExpression}] [DISTINCT] [TOTAL [<fld {,fld}>]] expr)
```

**Return data type:** integer

#### Arguments:

- **expr:** The expression or field containing the data to be measured.
- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT:** If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.

## 9 Script syntax and chart functions

- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Examples:

The following examples assume that all customers are selected, except where stated.

Examples and results

| Example                                                                                             | Result                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Count(OrderNumber)                                                                                  | 10, because there are 10 fields that could have a value for OrderNumber, and all records, even empty ones, are counted.<br><br><div style="border: 1px solid gray; padding: 5px; margin-top: 10px;">  "0" counts as a value and not an empty cell. However if a measure aggregates to 0 for a dimension that dimension will not be included in charts. </div> |
| Count (Customer)                                                                                    | 10, because Count evaluates the number of occurrences in all fields.                                                                                                                                                                                                                                                                                                                                                                           |
| Count (DISTINCT [Customer])                                                                         | 4, because using the Distinct qualifier, Count only evaluates unique occurrences.                                                                                                                                                                                                                                                                                                                                                              |
| Given that customer Canutility is selected<br><br>Count (OrderNumber)/Count ({1} TOTAL OrderNumber) | 0.2, because the expression returns the number of orders from the selected customer as a percentage of orders from all customers. In this case 2 / 10.                                                                                                                                                                                                                                                                                         |
| Given that customers Astrida and Canutility are selected<br><br>Count(TOTAL <Product> OrderNumber)  | 5, because that is the number of orders placed on products for the selected customers only and empty cells are counted.                                                                                                                                                                                                                                                                                                                        |

### MissingCount

**MissingCount()** returns the number of missing values aggregated in the expression, as defined by a **group by** clause.

#### Syntax:

```
MissingCount ([distinct] expr)
```

**Return data type:** integer

#### Arguments:

MissingCount arguments

| Argument | Description                                                                               |
|----------|-------------------------------------------------------------------------------------------|
| expr     | The expression or field containing the data to be measured.                               |
| distinct | If the word <b>distinct</b> occurs before the expression, all duplicates are disregarded. |

#### Examples and results:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in our document to see the result.

### Examples and results

| Example                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Result                                                                                                                                                                                                       |

### MissingCount

**MissingCount()** is used to aggregate the number of missing values in each chart dimension. Missing values are all non-numeric values.

#### Syntax:

```
MissingCount ([{SetExpression}] [DISTINCT] [TOTAL [<fld {,fld}>]] expr)
```

**Return data type:** integer

#### Arguments:

- **expr:** The expression or field containing the data to be measured.
- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT:** If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed

## 9 Script syntax and chart functions

by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Examples:

#### Examples and results

| Example                                                                   | Result                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MissingCount([OrderNumber])                                               | 3 because 3 of the 10 OrderNumber fields are empty<br><br><div style="border: 1px solid gray; padding: 5px;">  <i>"0" counts as a value and not an empty cell. However if a measure aggregates to 0 for a dimension that dimension will not be included in charts.</i> </div> |
| MissingCount<br>([OrderNumber])/MissingCount<br>({1} Total [OrderNumber]) | The expression returns the number of incomplete orders from the selected customer as a fraction of incomplete orders from all customers. There is a total of 3 missing values for OrderNumber for all customers. So, for each Customer that has a missing value for Product the result is 1/3.                                                                 |

### Data used in example:

```
Temp:

| Divadip    | DD      | 3           | -         | 25         |

### NullCount

**NullCount()** returns the number of NULL values aggregated in the expression, as defined by a **group by** clause.

#### Syntax:

```
NullCount ([distinct] expr)
```

**Return data type:** integer

#### Arguments:

##### NullCount arguments

| Argument | Description                                                                               |
|----------|-------------------------------------------------------------------------------------------|
| expr     | The expression or field containing the data to be measured.                               |
| distinct | If the word <b>distinct</b> occurs before the expression, all duplicates are disregarded. |

#### Examples and results:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in our document to see the result.

### Examples and results

| Example                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Result                                                                                                                                                                                                                         |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>Set NULLINTERPRET = NULL; Temp: LOAD * inline [ Customer Product OrderNumber UnitSales CustomerID Astrida AA 1 10 1 Astrida AA 7 18 1 Astrida BB 4 9 1 Astrida CC 6 2 1 Betacab AA 5 4 2 Betacab BB 2 5 2 Betacab DD    Canutility AA 3 8  Canutility CC NULL   ] (delimiter is ' '); Set NULLINTERPRET=; NullCount1: LOAD Customer,NullCount(OrderNumber) as NullOrdersByCustomer Resident Temp Group By Customer;  LOAD NullCount(OrderNumber) as TotalNullCount Resident Temp;</pre> | <pre>Customer NullOrdersByCustomer Astrida 0 Betacab 0 Canutility 1</pre> <p>The second statement gives:</p> <pre>TotalNullCount 1</pre> <p>in a table with that dimension, because only one record contains a null value.</p> |

### NullCount

**NullCount()** is used to aggregate the number of NULL values in each chart dimension.

#### Syntax:

```
NullCount ([{SetExpression}] [DISTINCT] [TOTAL [<fld {,fld}>]] expr)
```

**Return data type:** integer

#### Arguments:

- **expr:** The expression or field containing the data to be measured.
- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT:** If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Examples:

Examples and results

| Example                      | Result                                                                                             |
|------------------------------|----------------------------------------------------------------------------------------------------|
| NullCount<br>([OrderNumber]) | 1 because we have introduced a null value using NullInterpret in the inline <b>LOAD</b> statement. |

Data used in example:

```
Set NULLINTERPRET = NULL;
Temp:
LOAD * inline [
Customer|Product|OrderNumber|UnitSales|CustomerID
Astrida|AA|1|10|1
Astrida|AA|7|18|1
Astrida|BB|4|9|1
Astrida|CC|6|2|1
Betacab|AA|5|4|2
Betacab|BB|2|5|2
Betacab|DD|||
Canutility|AA|3|8|
Canutility|CC|NULL||
] (delimiter is '|');
Set NULLINTERPRET=;
```

### NumericCount

**NumericCount()** returns the number of numeric values found in the expression, as defined by a **group by** clause.

### Syntax:

```
NumericCount ([distinct] expr)
```

**Return data type:** integer

### Arguments:

NumericCount arguments

| Argument | Description                                                                               |
|----------|-------------------------------------------------------------------------------------------|
| expr     | The expression or field containing the data to be measured.                               |
| distinct | If the word <b>distinct</b> occurs before the expression, all duplicates are disregarded. |

### Examples and results:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in our document to see the result.

### Example 1:

Temp:

```
LOAD * inline [
Customer|Product|OrderNumber|UnitsSales|UnitPrice
Astrida|AA|1|4|16
Astrida|AA|7|10|15
Astrida|BB|4|9|9
Betacab|CC|6|5|10
Betacab|AA|5|2|20
Betacab|BB||| 25
Canutility|AA|||15
Canutility|CC| ||19
Divadip|CC|2|4|16
Divadip|DD|7|1|25
] (delimiter is '|');
NumCount1:
LOAD Customer, NumericCount(OrderNumber) as NumericCountByCustomer Resident Temp Group By
Customer;
```

Example 1 results

| Customer   | NumericCountByCustomer |
|------------|------------------------|
| Astrida    | 3                      |
| Betacab    | 2                      |
| Canutility | 0                      |
| Divadip    | 2                      |

### Example 2:

```
LOAD NumericCount(OrderNumber) as TotalNumericCount Resident Temp;
```

The second statement gives:

```
TotalNumericCount
7
```

### Example 3:

Given that the **Temp** table is loaded as in the previous example:

```
LOAD NumericCount(distinct OrderNumber) as TotalNumericCountDistinct Resident Temp;
TotalNumericCountDistinct
6
```

Because there is one OrderNumber that duplicates another, so the result is 6 distinct values.

### NumericCount

**NumericCount()** aggregates the number of numeric values in each chart dimension.

### Syntax:

```
NumericCount ([{SetExpression}] [DISTINCT] [TOTAL [<fld {, fld}>]] expr)
```

**Return data type:** integer

**Arguments:**

- `expr`: The expression or field containing the data to be measured.
- `SetExpression`: By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- `DISTINCT`: If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- `TOTAL`: If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets `<fld>`. These field names should be a subset of the chart dimension variables.

**Examples:**

The following examples assume that all customers are selected, except where stated.

Examples and results

| Example                                                                       | Result                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NumericCount<br>([OrderNumber])                                               | 7 because three of the 10 fields in OrderNumber are empty.<br><br><div style="border: 1px solid gray; padding: 5px; margin: 5px 0;">  "0" counts as a value and not an empty cell. However if a measure aggregates to 0 for a dimension that dimension will not be included in charts.         </div>            |
| NumericCount<br>([Product])                                                   | 0 because all product names are in text. Typically you could use this to check that no text fields have been given numeric content.                                                                                                                                                                                                                                                                 |
| NumericCount (DISTINCT<br>[OrderNumber])/Count<br>(DISTINCT<br>[OrderNumber]) | Counts all the number of distinct numeric order numbers and divides it by the number of order numbers numeric and non-numeric. This will be 1 if all field values are numeric. Typically you could use this to check that all field values are numeric. In the example, there are 7 distinct numeric values for OrderNumber of 8 distinct numeric and non-numeric, so the expression returns 0.875. |

Data used in example:

```
Temp:
LOAD * inline [
Customer|Product|OrderNumber|UnitSales|UnitPrice
Astrida|AA|1|4|16
Astrida|AA|7|10|15
Astrida|BB|4|9|9
Betacab|CC|6|5|10
```

```
Betacab|AA|5|2|20
Betacab|BB|1|25| 25
Canutility|AA|3|8|15
Canutility|CC|||19
Divadip|CC|2|4|16
Divadip|DD|3|1|25
] (delimiter is '|');
```

Example data in table form

| Customer   | Product | OrderNumber | UnitSales | Unit Price |
|------------|---------|-------------|-----------|------------|
| Astrida    | AA      | 1           | 4         | 16         |
| Astrida    | AA      | 7           | 10        | 15         |
| Astrida    | BB      | 4           | 9         | 9          |
| Betacab    | BB      | 6           | 5         | 10         |
| Betacab    | CC      | 5           | 2         | 20         |
| Betacab    | DD      | 1           | 25        | 25         |
| Canutility | AA      | 3           | 8         | 15         |
| Canutility | CC      | -           | -         | 19         |
| Divadip    | AA      | 2           | 4         | 16         |
| Divadip    | DD      | 3           | -         | 25         |

### TextCount

**TextCount()** returns the number of field values that are non-numeric aggregated in the expression, as defined by a **group by** clause.

#### Syntax:

```
TextCount ([distinct] expr)
```

**Return data type:** integer

#### Arguments:

TextCount arguments

| Argument | Description                                                                               |
|----------|-------------------------------------------------------------------------------------------|
| expr     | The expression or field containing the data to be measured.                               |
| distinct | If the word <b>distinct</b> occurs before the expression, all duplicates are disregarded. |

#### Examples and results:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in our document to see the result.

### Example 1:

```
Temp:
LOAD * inline [
Customer|Product|OrderNumber|UnitsSales|UnitPrice
Astrida|AA|1|4|16
Astrida|AA|7|10|15
Astrida|BB|4|9|9
Betacab|CC|6|5|10
Betacab|AA|5|2|20
Betacab|BB||| 25
Canutility|AA|||15
Canutility|CC| ||19
Divadip|CC|2|4|16
Divadip|DD|3|1|25
] (delimiter is '|');
TextCount1:
LOAD Customer,TextCount(Product) as ProductTextCount Resident Temp Group By Customer;
```

Example 1 results

| Customer   | ProductTextCount |
|------------|------------------|
| Astrida    | 3                |
| Betacab    | 3                |
| Canutility | 2                |
| Divadip    | 2                |

### Example 2:

```
LOAD Customer,TextCount(OrderNumber) as OrderNumberTextCount Resident Temp Group By Customer;
```

Example 2 results

| Customer   | OrderNumberTextCount |
|------------|----------------------|
| Astrida    | 0                    |
| Betacab    | 1                    |
| Canutility | 2                    |
| Divadip    | 0                    |

### TextCount - chart function

**TextCount()** is used to aggregate the number of field values that are non-numeric in each chart dimension.

#### Syntax:

```
TextCount ([{SetExpression}] [DISTINCT] [TOTAL [<fld {,fld}>]] expr)
```

**Return data type:** integer

**Arguments:**

- `expr`: The expression or field containing the data to be measured.
- `SetExpression`: By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- `DISTINCT`: If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- `TOTAL`: If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets `<fld>`. These field names should be a subset of the chart dimension variables.

**Examples:**

Examples and results

| Example                      | Result                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TextCount<br>([Product])     | 10 because all of the 10 fields in Product are text.<br><br><div style="border: 1px solid #ccc; padding: 5px; margin-top: 10px;">  <i>"0" counts as a value and not an empty cell. However if a measure aggregates to 0 for a dimension that dimension will not be included in charts.</i> </div> |
| TextCount<br>([OrderNumber]) | 3, because empty cells are counted. Typically, you would use this to check that no numeric fields have been given text values.                                                                                                                                                                                                                                                       |

**Data used in example:**

```
Temp:
LOAD * inline [
Customer|Product|OrderNumber|UnitsSales|UnitPrice
Astrida|AA|1|4|16
Astrida|AA|7|10|15
Astrida|BB|4|9|9
Betacab|CC|6|5|10
Betacab|AA|5|2|20
Betacab|BB|1|25| 25
Canutility|AA|3|8|15
Canutility|CC|||19
Divadip|CC|2|4|16
Divadip|DD|3|1|25
](delimiter is '|');
```

Example data in table form

| Customer   | Product | OrderNumber | UnitSales | Unit Price |
|------------|---------|-------------|-----------|------------|
| Astrida    | AA      | 1           | 4         | 16         |
| Astrida    | AA      | 7           | 10        | 15         |
| Astrida    | BB      | 4           | 9         | 9          |
| Betacab    | BB      | 6           | 5         | 10         |
| Betacab    | CC      | 5           | 2         | 20         |
| Betacab    | DD      | 1           | 25        | 25         |
| Canutility | AA      | 3           | 8         | 15         |
| Canutility | CC      | -           | -         | 19         |
| Divadip    | AA      | 2           | 4         | 16         |
| Divadip    | DD      | 3           | -         | 25         |

### Financial aggregation functions

This section describes aggregation functions for financial operations regarding payments and cash flow.

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

#### Financial aggregation functions in the load script

##### IRR

**IRR()** returns the aggregated internal rate of return for a series of cash flows represented by the numbers in the expression iterated over a number of records as defined by a group by clause.

```
IRR (expression)
```

##### XIRR

**XIRR()** returns the aggregated internal rate of return for a schedule of cash flows (that is not necessarily periodic) represented by paired numbers in **pmt** and **date** iterated over a number of records as defined by a group by clause. All payments are discounted based on a 365-day year.

```
XIRR (pmt, date)
```

##### NPV

**NPV()** returns the aggregated net present value of an investment based on a constant **discount\_rate** per period and a series of future payments (negative values) and incomes (positive values), represented by the numbers in **value**, iterated over a number of records, as defined by a group by clause. The payments and incomes are assumed to occur at the end of each period.

```
NPV (discount_rate, value)
```

### XNPV

**XNPV()** returns the aggregated net present value for a schedule of cashflows (not necessarily periodic) represented by paired numbers in **pmt** and **date**, iterated over a number of records as defined by a group by clause. Rate is the interest rate per period. All payments are discounted based on a 365-day year.

```
XNPV (discount_rate, pmt, date)
```

### Financial aggregation functions in chart expressions

These financial aggregation functions can be used in charts.

### IRR

**IRR()** returns the aggregated internal rate of return for a series of cash flows represented by the numbers in the expression given by **value** iterated over the chart dimensions.

```
IRR - chart function([TOTAL [<fld {,fld}>]] value)
```

### NPV

**NPV()** returns the aggregated net present value of an investment based on a **discount\_rate** per period and a series of future payments (negative values) and incomes (positive values,) represented by the numbers in **value**, iterated over the chart dimensions. The payments and incomes are assumed to occur at the end of each period.

```
NPV([TOTAL [<fld {,fld}>]] discount_rate, value)
```

### XIRR

**XIRR()** returns the aggregated internal rate of return for a schedule of cash flows (that is not necessarily periodic) represented by paired numbers in the expressions given by **pmt** and **date** iterated over the chart dimensions. All payments are discounted based on a 365-day year.

```
XIRR([TOTAL [<fld {,fld}>]] pmt, date)
```

### XNPV

**XNPV()** returns the aggregated net present value for a schedule of cash flows (not necessarily periodic) represented by paired numbers in the expressions given by **pmt** and **date** iterated over the chart dimensions. All payments are discounted based on a 365-day year.

```
XNPV([TOTAL [<fld{,fld}>]] discount_rate, pmt, date)
```

### IRR

**IRR()** returns the aggregated internal rate of return for a series of cash flows represented by the numbers in the expression iterated over a number of records as defined by a group by clause.

These cash flows do not have to be even, as they would be for an annuity. However, the cash flows must occur at regular intervals, such as monthly or annually. The internal rate of return is the interest rate received for an investment consisting of payments (negative values) and income (positive values) that occur at regular periods. The function needs at least one positive and one negative value to calculate.

This function uses a simplified version of the Newton method for calculating the internal rate of return (IRR).

### Syntax:

```
IRR (value)
```

**Return data type:** numeric

### Arguments:

- **value:** The expression or field containing the data to be measured.

### Limitations:

Text values, NULL values and missing values are disregarded.

### Examples and results:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

Cashflow:

```
LOAD 2013 as Year, * inline [
Date|Discount|Payments
2013-01-01|0.1|-10000
2013-03-01|0.1|3000
2013-10-30|0.1|4200
2014-02-01|0.2|6800
] (delimiter is '|');
```

Cashflow1:

```
LOAD Year,IRR(Payments) as IRR2013 Resident Cashflow Group By Year;
```

Example results

| Year | IRR2013 |
|------|---------|
| 2013 | 0.1634  |

### IRR - chart function

**IRR()** returns the aggregated internal rate of return for a series of cash flows represented by the numbers in the expression given by **value** iterated over the chart dimensions.

These cash flows do not have to be even, as they would be for an annuity. However, the cash flows must occur at regular intervals, such as monthly or annually. The internal rate of return is the interest rate received for an investment consisting of payments (negative values) and income (positive values) that occur at regular periods. The function needs at least one positive and one negative value to calculate.

This function uses a simplified version of the Newton method for calculating the internal rate of return (IRR).

### Syntax:

```
IRR ([TOTAL [<fld {,fld}>]] value)
```

**Return data type:** numeric

### Arguments:

- **value:** The expression or field containing the data to be measured.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Limitations:

The parameter of the aggregation function must not contain other aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

Text values, NULL values and missing values are disregarded.

### Examples and results:

`IRR(Payments): 0.1634.`

The payments are assumed to be periodic in nature, for example monthly.

*For non-periodic payments, please refer to the **XIRR** function.*

### Data used in examples:

Cashflow:

```
LOAD 2013 as Year, * inline [
Date|Discount|Payments
2013-01-01|0.1|-10000
2013-03-01|0.1|3000
2013-10-30|0.1|4200
2014-02-01|0.2|6800
(delimiter is '|');
```

### NPV

**NPV()** returns the aggregated net present value of an investment based on a constant **discount\_rate** per period and a series of future payments (negative values) and incomes (positive values), represented by the numbers in **value**, iterated over a number of records, as defined by a group by clause. The payments and incomes are assumed to occur at the end of each period.

### Syntax:

```
NPV(discount_rate, value)
```

**Return data type:** numeric. The result has a default number format of money.

**Arguments:**

- `discount_rate`: **discount\_rate** is the rate of discount over the length of the period. **discount\_rate** is a constant.
- `value`: The expression or field containing the data to be measured.

**Limitations:**

Text values, NULL values and missing values are disregarded.

**Examples and results:**

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

Cashflow:

```
LOAD 2013 as Year, * inline [
Date|Discount|Payments
2013-01-01|0.1|-10000
2013-03-01|0.1|3000
2013-10-30|0.1|4200
2014-02-01|0.2|6800
] (delimiter is '|');
```

Cashflow1:

```
LOAD Year,NPV(0.2, Payments) as NPV1_2013 Resident Cashflow Group By Year;
```

Example results

| Year | NPV1_2013 |
|------|-----------|
| 2013 | -\$540.12 |

Given that the **Cashflow** table is loaded as in the previous example:

```
LOAD Year,NPV(Discount, Payments) as NPV2_2013 Resident Cashflow Group By Year, Discount;
```

Example results

| Year | Discount | NPV2_2013  |
|------|----------|------------|
| 2013 | 0.1      | -\$3456.05 |
| 2013 | 0.2      | \$5666.67  |

| Example                                                                                                                                                                                                                                                                                                      | Result field                                         | Result value                             |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|------------------------------------------|
| <b>Cashflow:</b><br>LOAD 2013 as Year, * inline [<br>Date Discount Payments<br>2013-01-01 0.1 -10000<br>2013-03-01 0.1 3000<br>2013-10-30 0.1 4200<br>2014-02-01 0.2 6800<br>] (delimiter is ' ');<br><br><b>Cashflow1:</b><br>LOAD Year,NPV(0.2, Payments) as NPV1_2013<br>Resident Cashflow Group By Year; | Year<br><br>2013                                     | NPV1_2013<br><br>-\$540.12               |
| Given that the <b>Cashflow</b> table is loaded as in the previous example:<br>LOAD Year,NPV(Discount, Payments) as NPV2_2013<br>Resident Cashflow Group By Year, Discount;                                                                                                                                   | Year      Discount<br>2013      0.1<br>2013      0.2 | NPV2_2013<br><br>-\$3456.05<br>\$5666.67 |

### NPV

**NPV()** returns the aggregated net present value of an investment based on a **discount\_rate** per period and a series of future payments (negative values) and incomes (positive values,) represented by the numbers in **value**, iterated over the chart dimensions. The payments and incomes are assumed to occur at the end of each period.

#### Syntax:

```
NPV ([TOTAL [<fld {,fld}>]] discount_rate, value)
```

**Return data type:** numeric. The result has a default number format of money.

#### Arguments:

- **discount\_rate:** **discount\_rate** is the rate of discount over the length of the period.
- **value:** The expression or field containing the data to be measured.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.  
The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets. For example: Sum(**TOTAL** <Quarter> {<Year={2013}, Quarter={'Q2'}>} Amount) These field names should be a subset of the chart dimensions. In this case, the calculation is made disregarding all chart dimensions except those listed, that is, one value is returned for each combination of field values in the listed dimension fields. Also, fields that are not currently a dimension in a chart may be included in the list. This may be useful in the case of group dimensions, where the dimension fields are not fixed. Listing all of the dimensions in the group causes the function to give consistent aggregation results when the drill-down level changes.

### Limitations:

**discount\_rate** and **value** must not contain aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

Text values, NULL values and missing values are disregarded.

### Examples and results:

```
NPV(Discount, Payments): -$540.12.
```

### Data used in examples:

```
Cashflow:
LOAD 2013 as Year, * inline [
Date|Discount|Payments
2013-01-01|0.1|-10000
2013-03-01|0.1|3000
2013-10-30|0.1|4200
2014-02-01|0.2|6800
] (delimiter is '|');
```

### XIRR

**XIRR()** returns the aggregated internal rate of return for a schedule of cash flows (that is not necessarily periodic) represented by paired numbers in **pmt** and **date** iterated over a number of records as defined by a group by clause. All payments are discounted based on a 365-day year.

Qlik's XIRR functionality (**XIRR()** and **RangeXIRR()** functions) uses the following equation, solving for the rate value, to determine the correct XIRR value:

$$\text{XNPV}(\text{Rate}, \text{pmt}, \text{date}) = 0$$

The equation is solved using a simplified version of the Newton method.

### Syntax:

```
XIRR(pmt, date)
```

**Return data type:** numeric

### Arguments:

- **pmt:** Payments. The expression or field containing the cash flows corresponding to the payment schedule given in **date**.
- **date:** The expression or field containing the schedule of dates corresponding to the cash flow payments given in **pmt**.

### Limitations:

Text values, NULL values and missing values in any or both pieces of a data-pair will result in the entire data-pair to be disregarded.

### Examples and results:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
Cashflow:
LOAD 2013 as Year, * inline [
Date|Discount|Payments
2013-01-01|0.1|-10000
2013-03-01|0.1|3000
2013-10-30|0.1|4200
2014-02-01|0.2|6800
] (delimiter is '|');
```

```
Cashflow1:
LOAD Year,XIRR(Payments, Date) as XIRR2013 Resident Cashflow Group By Year;
```

Example results

| Year | XIRR2013 |
|------|----------|
| 2013 | 0.5385   |

### XIRR

**XIRR()** returns the aggregated internal rate of return for a schedule of cash flows (that is not necessarily periodic) represented by paired numbers in the expressions given by **pmt** and **date** iterated over the chart dimensions. All payments are discounted based on a 365-day year.

Qlik's XIRR functionality (**XIRR()** and **RangeXIRR()** functions) uses the following equation, solving for the Rate value, to determine the correct XIRR value:

$$\text{XNPV}(\text{Rate}, \text{pmt}, \text{date}) = 0$$

The equation is solved using a simplified version of the Newton method.

### Syntax:

```
XIRR ([TOTAL [<fld {,fld}>]] pmt, date)
```

**Return data type:** numeric

### Arguments:

- **pmt:** Payments. The expression or field containing the cash flows corresponding to the payment schedule given in **date**.
- **date:** The expression or field containing the schedule of dates corresponding to the cash flow payments given in **pmt**.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed

by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Limitations:

**pmt** and **date** must not contain aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

### Examples and results:

```
XIRR(Payments, Date): 0.5385.
```

### Data used in examples:

```
Cashflow:
LOAD 2013 as Year, * inline [
Date|Discount|Payments
2013-01-01|0.1|-10000
2013-03-01|0.1|3000
2013-10-30|0.1|4200
2014-02-01|0.2|6800
] (delimiter is '|');
```

### XNPV

**XNPV()** returns the aggregated net present value for a schedule of cashflows (not necessarily periodic) represented by paired numbers in **pmt** and **date**, iterated over a number of records as defined by a group by clause. Rate is the interest rate per period. All payments are discounted based on a 365-day year.

### Syntax:

```
XNPV(discount_rate, pmt, date)
```

**Return data type:** numeric. The result has a default number format of money. .

### Arguments:

- **pmt**: The expression or field containing the data to be measured.
- **date**: The expression or field containing the schedule of dates corresponding to the cash flow payments given in **pmt**.
- **discount\_rate**: **discount\_rate** is the rate of discount over the length of the period.

### Limitations:

Text values, NULL values and missing values in any or both pieces of a data-pair will result in the entire data-pair to be disregarded.

### Examples and results:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
Cashflow:
LOAD 2013 as Year, * inline [
Date|Discount|Payments
2013-01-01|0.1|-10000
2013-03-01|0.1|3000
2013-10-30|0.1|4200
2014-02-01|0.2|6800
] (delimiter is '|');
```

```
Cashflow1:
LOAD Year,XNPV(0.2, Payments, Date) as XNPV1_2013 Resident Cashflow Group By Year;
```

Example results

| Year | XNPV1_2013 |
|------|------------|
| 2013 | \$2104.37  |

Given that the **Cashflow** table is loaded as in the previous example:

```
LOAD Year,XNPV(Discount, Payments, Date) as XNPV2_2013 Resident Cashflow Group By Year,
Discount;
```

Example results

| Year | Discount | XNPV2_2013 |
|------|----------|------------|
| 2013 | 0.1      | -\$3164.35 |
| 2013 | 0.2      | \$6800.00  |

### XNPV

**XNPV()** returns the aggregated net present value for a schedule of cash flows (not necessarily periodic) represented by paired numbers in the expressions given by **pmt** and **date** iterated over the chart dimensions. All payments are discounted based on a 365-day year.

### Syntax:

```
XNPV ([TOTAL [<fld{,fld}>]] discount_rate, pmt, date)
```

**Return data type:** numeric The result has a default number format of money.

### Arguments:

- **pmt:** The expression or field containing the data to be measured.
- **date:** The expression or field containing the schedule of dates corresponding to the cash flow payments given in **pmt**.
- **discount\_rate:** **discount\_rate** is the rate of discount over the length of the period.

- **TOTAL**: If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Limitations:

**discount\_rate**, **pmt** and **date** must not contain aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

### Examples and results:

XNPV(Discount, Payments, Date): **-\$3164.35**.

### Data used in examples:

```
Cashflow:
LOAD 2013 as Year, * inline [
Date|Discount|Payments
2013-01-01|0.1|-10000
2013-03-01|0.1|3000
2013-10-30|0.1|4200
2014-02-01|0.2|6800
] (delimiter is '|');
```

## Statistical aggregation functions

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

### Statistical aggregation functions in the load script

The following statistical aggregation functions can be used in scripts.

#### Avg

**Avg()** finds the average value of the aggregated data in the expression over a number of records as defined by a **group by** clause.

```
Avg ([distinct] expression)
```

#### Correl

**Correl()** returns the aggregated correlation coefficient for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

```
Correl (x-expression, y-expression)
```

### Fractile

**Fractile()** finds the value that corresponds to the inclusive fractile (quantile) of the aggregated data in the expression over a number of records as defined by a **group by** clause.

```
Fractile (expression, fractile)
```

### FractileExc

**FractileExc()** finds the value that corresponds to the exclusive fractile (quantile) of the aggregated data in the expression over a number of records as defined by a **group by** clause.

```
FractileExc (expression, fractile)
```

### Kurtosis

**Kurtosis()** returns the kurtosis of the data in the expression over a number of records as defined by a **group by** clause.

```
Kurtosis ([distinct] expression)
```

### LINEST\_B

**LINEST\_B()** returns the aggregated b value (y-intercept) of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

```
LINEST_B (y-expression, x-expression [, y0 [, x0]])
```

### LINEST\_df

**LINEST\_DF()** returns the aggregated degrees of freedom of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

```
LINEST_DF (y-expression, x-expression [, y0 [, x0]])
```

### LINEST\_f

This script function returns the aggregated F statistic ( $r^2/(1-r^2)$ ) of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

```
LINEST_F (y-expression, x-expression [, y0 [, x0]])
```

### LINEST\_m

**LINEST\_M()** returns the aggregated m value (slope) of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

```
LINEST_M (y-expression, x-expression [, y0 [, x0]])
```

### LINEST\_r2

**LINEST\_R2()** returns the aggregated  $r^2$  value (coefficient of determination) of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

```
LINEST_R2 (y-expression, x-expression [, y0 [, x0]])
```

### **LINEST\_seb**

**LINEST\_SEB()** returns the aggregated standard error of the b value of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

```
LINEST_SEB (y-expression, x-expression [, y0 [, x0]])
```

### **LINEST\_sem**

**LINEST\_SEM()** returns the aggregated standard error of the m value of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

```
LINEST_SEM (y-expression, x-expression [, y0 [, x0]])
```

### **LINEST\_sey**

**LINEST\_SEY()** returns the aggregated standard error of the y estimate of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

```
LINEST_SEY (y-expression, x-expression [, y0 [, x0]])
```

### **LINEST\_ssreg**

**LINEST\_SSREG()** returns the aggregated regression sum of squares of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

```
LINEST_SSREG (y-expression, x-expression [, y0 [, x0]])
```

### **Linest\_ssresid**

**LINEST\_SSRESID()** returns the aggregated residual sum of squares of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

```
LINEST_SSRESID (y-expression, x-expression [, y0 [, x0]])
```

### **Median**

**Median()** returns the aggregated median of the values in the expression over a number of records as defined by a **group by** clause.

```
Median (expression)
```

### **Skew**

**Skew()** returns the skewness of expression over a number of records as defined by a **group by** clause.

```
Skew ([distinct] expression)
```

### Stdev

**Stdev()** returns the standard deviation of the values given by the expression over a number of records as defined by a **group by** clause.

```
Stdev ([distinct] expression)
```

### Sterr

**Sterr()** returns the aggregated standard error (stdev/sqrt(n)) for a series of values represented by the expression iterated over a number of records as defined by a **group by** clause.

```
Sterr ([distinct] expression)
```

### STEYX

**STEYX()** returns the aggregated standard error of the predicted y-value for each x-value in the regression for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

```
STEYX (y-expression, x-expression)
```

### Statistical aggregation functions in chart expressions

The following statistical aggregation functions can be used in charts.

#### Avg

**Avg()** returns the aggregated average of the expression or field iterated over the chart dimensions.

```
Avg - chart function([SetExpression] [DISTINCT] [TOTAL [<fld{, fld}>]]
expr)
```

#### Correl

**Correl()** returns the aggregated correlation coefficient for two data sets. The correlation function is a measure of the relationship between the data sets and is aggregated for (x,y) value pairs iterated over the chart dimensions.

```
Correl - chart function([SetExpression] [TOTAL [<fld {, fld}>]] value1,
value2)
```

#### Fractile

**Fractile()** finds the value that corresponds to the inclusive fractile (quantile) of the aggregated data in the range given by the expression iterated over the chart dimensions.

```
Fractile - chart function([SetExpression] [TOTAL [<fld {, fld}>]] expr,
fraction)
```

#### FractileExc

**FractileExc()** finds the value that corresponds to the exclusive fractile (quantile) of the aggregated data in the range given by the expression iterated over the chart dimensions.

```
FractileExc - chart function([SetExpression] [TOTAL [<fld {, fld}>]] expr,
fraction)
```

Kurtosis

**Kurtosis()** finds the kurtosis of the range of data aggregated in the expression or field iterated over the chart dimensions.

```
Kurtosis - chart function([{SetExpression}] [DISTINCT] [TOTAL [<fld{, fld}>]]
expr)
```

LINEST\_b

**LINEST\_B()** returns the aggregated b value (y-intercept) of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in the expressions given by the expressions **x\_value** and **y\_value**, iterated over the chart dimensions.

```
LINEST_B - chart function([{SetExpression}] [TOTAL [<fld{, fld}>]] y_value,
x_value[, y0_const[, x0_const]])
```

LINEST\_df

**LINEST\_DF()** returns the aggregated degrees of freedom of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in the expressions given by **x\_value** and **y\_value**, iterated over the chart dimensions.

```
LINEST_DF - chart function([{SetExpression}] [TOTAL [<fld{, fld}>]] y_value,
x_value [, y0_const [, x0_const]])
```

LINEST\_f

**LINEST\_F()** returns the aggregated F statistic ( $r^2/(1-r^2)$ ) of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in the expressions given by **x\_value** and the **y\_value**, iterated over the chart dimensions.

```
LINEST_F - chart function([{SetExpression}] [TOTAL [<fld{, fld}>]] y_value, x_
value [, y0_const [, x0_const]])
```

LINEST\_m

**LINEST\_M()** returns the aggregated m value (slope) of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers given by the expressions **x\_value** and **y\_value**, iterated over the chart dimensions.

```
LINEST_M - chart function([{SetExpression}] [TOTAL [<fld{, fld}>]] y_value, x_
value [, y0_const [, x0_const]])
```

LINEST\_r2

**LINEST\_R2()** returns the aggregated r2 value (coefficient of determination) of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers given by the expressions **x\_value** and **y\_value**, iterated over the chart dimensions.

```
LINEST_R2 - chart function([{SetExpression}] [TOTAL [<fld{, fld}>]] y_value,
x_value[, y0_const[, x0_const]])
```

### LINEST\_seb

**LINEST\_SEB()** returns the aggregated standard error of the b value of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers given by the expressions **x\_value** and **y\_value**, iterated over the chart dimensions.

```
LINEST_SEB - chart function([SetExpression] [TOTAL [<fld{ ,fld}>]] y_value, x_value[, y0_const[, x0_const]])
```

### LINEST\_sem

**LINEST\_SEM()** returns the aggregated standard error of the m value of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers given by the expressions **x\_value** and **y\_value**, iterated over the chart dimensions.

```
LINEST_SEM - chart function([set_expression][distinct] [total [<fld{ ,fld}>]] y-expression, x-expression [, y0 [, x0]])
```

### LINEST\_sey

**LINEST\_SEY()** returns the aggregated standard error of the y estimate of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers given by the expressions **x\_value** and **y\_value**, iterated over the chart dimensions.

```
LINEST_SEY - chart function([SetExpression] [TOTAL [<fld{ ,fld}>]] y_value, x_value[, y0_const[, x0_const]])
```

### LINEST\_ssreg

**LINEST\_SSREG()** returns the aggregated regression sum of squares of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers given by the expressions **x\_value** and **y\_value**, iterated over the chart dimensions.

```
LINEST_SSREG - chart function([SetExpression] [TOTAL [<fld{ ,fld}>]] y_value, x_value[, y0_const[, x0_const]])
```

### LINEST\_ssresid

**LINEST\_SSRESID()** returns the aggregated residual sum of squares of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in the expressions given by **x\_value** and **y\_value**, iterated over the chart dimensions.

```
LINEST_SSRESID - chart function([SetExpression] [TOTAL [<fld{ ,fld}>]] y_value, x_value[, y0_const[, x0_const]])
```

### Median

**Median()** returns the median value of the range of values aggregated in the expression iterated over the chart dimensions.

```
Median - chart function([SetExpression] [TOTAL [<fld{ , fld}>]] expr)
```

### MutualInfo

**MutualInfo** calculates the mutual information (MI) between two fields or between aggregated values in **Aggr()**.

## 9 Script syntax and chart functions

```
MutualInfo - chart function({SetExpression}} [DISTINCT] [TOTAL target, driver
[, datatype [, breakdownbyvalue [, samplesize]]])
```

Skew

**Skew()** returns the aggregated skewness of the expression or field iterated over the chart dimensions.

```
Skew - chart function({SetExpression}} [DISTINCT] [TOTAL [<fld{ , fld}>]]
expr)
```

Stdev

**Stdev()** finds the standard deviation of the range of data aggregated in the expression or field iterated over the chart dimensions.

```
Stdev - chart function({SetExpression}} [DISTINCT] [TOTAL [<fld{ , fld}>]]
expr)
```

Sterr

**Sterr()** finds the value of the standard error of the mean, (stdev/sqrt(n)), for the series of values aggregated in the expression iterated over the chart dimensions.

```
Sterr - chart function({SetExpression}} [DISTINCT] [TOTAL [<fld{ , fld}>]]
expr)
```

STEYX

**STEYX()** returns the aggregated standard error when predicting y-values for each x-value in a linear regression given by a series of coordinates represented by paired numbers in the expressions given by **y\_value** and **x\_value**.

```
STEYX - chart function({SetExpression}} [TOTAL [<fld{ , fld}>]] y_value, x_
value)
```

Avg

**Avg()** finds the average value of the aggregated data in the expression over a number of records as defined by a **group by** clause.

**Syntax:**

```
Avg ([DISTINCT] expr)
```

**Return data type:** numeric

**Arguments:**

Avg arguments

| Argument | Description                                                                                   |
|----------|-----------------------------------------------------------------------------------------------|
| expr     | The expression or field containing the data to be measured.                                   |
| DISTINCT | If the word <b>distinct</b> occurs before the expression, all duplicates will be disregarded. |

### Examples and results:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

Examples and results

| Example                                                                                                                                                                                                                                                                                                                                                                                                                 | Result                                                                                                                                                                                                            |

### Avg - chart function

**Avg()** returns the aggregated average of the expression or field iterated over the chart dimensions.

#### Syntax:

```
Avg ([{SetExpression}] [DISTINCT] [TOTAL [<fld{, fld}>]] expr)
```

**Return data type:** numeric

#### Arguments:

- **expr:** The expression or field containing the data to be measured.
- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT:** If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current

## 9 Script syntax and chart functions

dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Limitations:

The parameter of the aggregation function must not contain other aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

### Examples:

#### Examples and results

| Example               | Result                                                                                                                           |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------|
| Avg(Sales)            | For a table including the dimension customer and the measure Avg([Sales]), if <b>Totals</b> are shown, the result is 2566.       |
| Avg([TOTAL (Sales)])  | 53.458333 for all values of customer, because the TOTAL qualifier means that dimensions are disregarded.                         |
| Avg(DISTINCT (Sales)) | 51.862069 for the total, because using the Distinct qualifier means only unique values in sales for each customer are evaluated. |

#### Example output in table form

| Customer   | Sum (Sales) | Avg (Sales) | Avg(TOTAL Sales) | Avg(DISTINCT Sales) | Avg({1}DISTINCT Sales) |
|------------|-------------|-------------|------------------|---------------------|------------------------|
| -          | 2566        | 53.46       | 53.458333        | 51.862069           | 53.458333              |
| Astrida    | 587         | 48.92       | 53.458333        | 43.1                | 53.458333              |
| Betacab    | 539         | 44.92       | 53.458333        | 43.909091           | 53.458333              |
| Canutility | 683         | 56.92       | 53.458333        | 55.909091           | 53.458333              |
| Divadip    | 757         | 63.08       | 53.458333        | 61                  | 53.458333              |

### Data used in examples:

### Correl

**Correl()** returns the aggregated correlation coefficient for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

### Syntax:

```
Correl (value1, value2)
```

**Return data type:** numeric

### Arguments:

Correl arguments

| Argument          | Description                                                                                                       |
|-------------------|-------------------------------------------------------------------------------------------------------------------|
| value1,<br>value2 | The expressions or fields containing the two sample sets for which the correlation coefficient is to be measured. |

### Limitations:

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

### Examples and results:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

### Examples and results

| Example                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Result                               |

### Correl - chart function

**Correl()** returns the aggregated correlation coefficient for two data sets. The correlation function is a measure of the relationship between the data sets and is aggregated for (x,y) value pairs iterated over the chart dimensions.

#### Syntax:

```
Correl ([{SetExpression}] [DISTINCT] [TOTAL [<fld{, fld}>]] value1, value2)
```

**Return data type:** numeric

#### Arguments:

- **value1, value2:** The expressions or fields containing the two sample sets for which the correlation coefficient is to be measured.
- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT:** If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Limitations:

The parameter of the aggregation function must not contain other aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

### Examples:

Examples and results

| Example                    | Result                                                                                                                                                            |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Correl(Age, Salary)        | For a table including the dimension Employee name and the measure Correl(Age, Salary), the result is 0.9270611. The result is only displayed for the totals cell. |
| Correl(TOTAL Age, Salary)) | 0.927. This and the following results are shown to three decimal places for readability.                                                                          |

### Data used in examples:

```
Salary:
LOAD * inline [
"Employee name"|Gender|Age|Salary
Aiden Charles|Male|20|25000
Brenda Davies|Male|25|32000
Charlotte Edberg|Female|45|56000
Daroush Ferrara|Male|31|29000
Eunice Goldblum|Female|31|32000
Freddy Halvorsen|Male|25|26000
Gauri Indu|Female|36|46000
Harry Jones|Male|38|40000
Ian Underwood|Male|40|45000
Jackie Kingsley|Female|23|28000
] (delimiter is '|');
```

### Fractile

**Fractile()** finds the value that corresponds to the inclusive fractile (quantile) of the aggregated data in the expression over a number of records as defined by a **group by** clause.

You can use *FractileExc* (page 1111) to calculate the exclusive fractile.

### Syntax:

```
Fractile(expr, fraction)
```

**Return data type:** numeric

The function returns the value corresponding to the rank as defined by  $\text{rank} = \text{fraction} * (N-1) + 1$  where  $N$  is the number of values in `expr`. If rank is a non-integer number, an interpolation is made between the two closest values.

**Arguments:**

Fractile arguments

| Argument              | Description                                                                                                 |
|-----------------------|-------------------------------------------------------------------------------------------------------------|
| <code>expr</code>     | The expression or field containing the data to use when calculating the fractile.                           |
| <code>fraction</code> | A number between 0 and 1 corresponding to the fractile (quantile expressed as a fraction) to be calculated. |

**Examples and results:**

Add the example script to your app and run it. To see the result, add the fields listed in the results column to a sheet in your app.

### Examples and results

| Example                                                                                                                                                                                                                                                                                                                     | Result                                                                                                                                                                                       |

### Fractile - chart function

**Fractile()** finds the value that corresponds to the inclusive fractile (quantile) of the aggregated data in the range given by the expression iterated over the chart dimensions.

You can use *FractileExc* - chart function (page 1113) to calculate the exclusive fractile.

### Syntax:

```
Fractile ([{SetExpression}] [DISTINCT] [TOTAL [<fld{, fld}>]] expr, fraction)
```

### Return data type: numeric

The function returns the value corresponding to the rank as defined by  $\text{rank} = \text{fraction} * (N-1) + 1$  where  $N$  is the number of values in *expr*. If rank is a non-integer number, an interpolation is made between the two closest values.

### Arguments:

- `expr`: The expression or field containing the data to use when calculating the fractile.
- `fraction`: A number between 0 and 1 corresponding to the fractile (quantile expressed as a fraction) to be calculated.
- `SetExpression`: By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- `DISTINCT`: If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- `TOTAL`: If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. By using **TOTAL [<fld {fld}>]**, where the **TOTAL** qualifier is followed by a list of one or more field names as a subset of the chart dimension variables, you create a subset of the total possible values.

### Limitations:

The parameter of the aggregation function must not contain other aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

### Examples:

Examples and results

| Example                                  | Result                                                                                                                                                                                                                                                                 |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fractile<br>(Sales,<br>0.75)             | For a table including the dimension <code>customer</code> and the measure <code>Fractile([Sales])</code> , if <b>Totals</b> are shown, the result is 71.75. This is the point in the distribution of values of <code>sales</code> that 75% of the values fall beneath. |
| Fractile<br>(TOTAL<br>Sales,<br>0.75))   | 71.75 for all values of <code>customer</code> , because the <b>TOTAL</b> qualifier means that dimensions are disregarded.                                                                                                                                              |
| Fractile<br>(DISTINCT<br>Sales,<br>0.75) | 70 for the total, because using the <b>DISTINCT</b> qualifier means only unique values in <code>sales</code> for each <code>customer</code> are evaluated.                                                                                                             |

### FractileExc

**FractileExc()** finds the value that corresponds to the exclusive fractile (quantile) of the aggregated data in the expression over a number of records as defined by a **group by** clause.

You can use *Fractile* (page 1107) to calculate the inclusive fractile.

### Syntax:

```
FractileExc(expr, fraction)
```

**Return data type:** numeric

The function returns the value corresponding to the rank as defined by  $\text{rank} = \text{fraction} * (N+1)$  where  $N$  is the number of values in *expr*. If rank is a non-integer number, an interpolation is made between the two closest values.

### Arguments:

FractileExc arguments

| Argument | Description                                                                                                 |
|----------|-------------------------------------------------------------------------------------------------------------|
| expr     | The expression or field containing the data to use when calculating the fractile.                           |
| fraction | A number between 0 and 1 corresponding to the fractile (quantile expressed as a fraction) to be calculated. |

### Examples and results:

Add the example script to your app and run it. To see the result, add the fields listed in the results column to a sheet in your app.

Examples and results

| Example                                                                                                                                                                                                                                                                                                                        | Result                                                                                                                                                                                                                                 |

### FractileExc - chart function

**FractileExc()** finds the value that corresponds to the exclusive fractile (quantile) of the aggregated data in the range given by the expression iterated over the chart dimensions.

You can use *Fractile - chart function* (page 1109) to calculate the inclusive fractile.

#### Syntax:

```
FractileExc ([{SetExpression}] [DISTINCT] [TOTAL [<fld{, fld}>]] expr,
fraction)
```

**Return data type:** numeric

The function returns the value corresponding to the rank as defined by  $\text{rank} = \text{fraction} * (N+1)$  where  $N$  is the number of values in *expr*. If rank is a non-integer number, an interpolation is made between the two closest values.

#### Arguments:

- *expr*: The expression or field containing the data to use when calculating the fractile.
- *fraction*: A number between 0 and 1 corresponding to the fractile (quantile expressed as a fraction) to be calculated.
- *SetExpression*: By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT**: If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- **TOTAL**: If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. By using **TOTAL [<fld {, fld}>]**, where the **TOTAL** qualifier is followed by a list of one or more field names as a subset of the chart dimension variables, you create a subset of the total possible values.

#### Limitations:

The parameter of the aggregation function must not contain other aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

### Examples:

Examples and results

| Example                                  | Result                                                                                                                                                                                                                            |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FractileExc<br>(Sales, 0.75)             | For a table including the dimension Customer and the measure FractileExc([Sales]), if <b>Totals</b> are shown, the result is 75.25. This is the point in the distribution of values of sales that 75% of the values fall beneath. |
| FractileExc<br>(TOTAL Sales,<br>0.75))   | 75.25 for all values of Customer, because the TOTAL qualifier means that dimensions are disregarded.                                                                                                                              |
| FractileExc<br>(DISTINCT<br>Sales, 0.75) | 73.50 for the total, because using the DISTINCT qualifier means only unique values in sales for each customer are evaluated.                                                                                                      |

### Kurtosis

**Kurtosis()** returns the kurtosis of the data in the expression over a number of records as defined by a **group by** clause.

### Syntax:

```
Kurtosis([distinct] expr)
```

**Return data type:** numeric

### Arguments:

#### Kurtosis arguments

| Argument | Description                                                                                   |
|----------|-----------------------------------------------------------------------------------------------|
| expr     | The expression or field containing the data to be measured.                                   |
| distinct | If the word <b>distinct</b> occurs before the expression, all duplicates will be disregarded. |

### Examples and results:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

### Examples and results

| Example                                                                                                                                                                                                                                                                                                                                            | Result                                                                                                                                                                                                                                                   |

### Kurtosis - chart function

**Kurtosis()** finds the kurtosis of the range of data aggregated in the expression or field iterated over the chart dimensions.

#### Syntax:

```
Kurtosis ([{SetExpression}] [DISTINCT] [TOTAL [<fld{, fld}>]] expr)
```

**Return data type:** numeric

#### Arguments:

- **expr:** The expression or field containing the data to be measured.

- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT:** If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Limitations:

The parameter of the aggregation function must not contain other aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

### Examples:

Examples and results

| Example                | Result                                                                                                                                                                                                                                               |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Kurtosis (value)       | For a table including the dimension type and the measure kurtosis(value), if Totals are shown for the table, and number formatting is set to 3 significant figures, the result is 1.252. For comparison it is 1.161 and for observation it is 1.115. |
| Kurtosis (TOTAL value) | 1.252 for all values of type, because the TOTAL qualifier means that dimensions are disregarded.                                                                                                                                                     |

### Data used in examples:

```

### LINEST\_B

**LINEST\_B()** returns the aggregated b value (y-intercept) of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

#### Syntax:

```
LINEST_B (y-value, x-value[, y0 [, x0]])
```

**Return data type:** numeric

#### Arguments:

LINEST\_B arguments

| Argument   | Description                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y_value    | The expression or field containing the range of y-values to be measured.                                                                                                                                                                                                                                                                                                                     |
| x_value    | The expression or field containing the range of x-values to be measured.                                                                                                                                                                                                                                                                                                                     |
| y(0), x(0) | An optional value y0 may be stated forcing the regression line to pass through the y-axis at a given point. By stating both y0 and x0 it is possible to force the regression line to pass through a single fixed coordinate.<br><br>Unless both y0 and x0 are stated, the function requires at least two valid data-pairs to calculate. If y0 and x0 are stated, a single data pair will do. |

#### Limitations:

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

### LINEST\_B - chart function

**LINEST\_B()** returns the aggregated b value (y-intercept) of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in the expressions given by the expressions **x\_value** and **y\_value**, iterated over the chart dimensions.

#### Syntax:

```
LINEST_B ([{SetExpression}] [DISTINCT] [TOTAL [<fld{, fld}>]] y_value, x_value
[, y0_const [, x0_const]])
```

**Return data type:** numeric

**Arguments:**

- **y\_value:** The expression or field containing the range of y-values to be measured.
- **x\_value:** The expression or field containing the range of x-values to be measured.
- **y0\_const,x0\_const:** An optional value y0 may be stated forcing the regression line to pass through the y-axis at a given point. By stating both y0 and x0 it is possible to force the regression line to pass through a single fixed coordinate.

*Unless both y0 and x0 are stated, the function requires at least two valid data-pairs to calculate. If y0 and x0 are stated, a single data pair will do.*

- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT:** If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

**Limitations:**

The parameter of the aggregation function must not contain other aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

### LINEST\_DF

**LINEST\_DF()** returns the aggregated degrees of freedom of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

**Syntax:**

```
LINEST_DF (y-value, x-value[, y0 [, x0]])
```

**Return data type:** numeric

**Arguments:**

LINEST\_DF arguments

| Argument   | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y_value    | The expression or field containing the range of y-values to be measured.                                                                                                                                                                                                                                                                                                                            |
| x_value    | The expression or field containing the range of x-values to be measured.                                                                                                                                                                                                                                                                                                                            |
| y(0), x(0) | <p>An optional value y0 may be stated forcing the regression line to pass through the y-axis at a given point. By stating both y0 and x0 it is possible to force the regression line to pass through a single fixed coordinate.</p> <p>Unless both y0 and x0 are stated, the function requires at least two valid data-pairs to calculate. If y0 and x0 are stated, a single data pair will do.</p> |

**Limitations:**

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

LINEST\_DF - chart function

**LINEST\_DF()** returns the aggregated degrees of freedom of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in the expressions given by **x\_value** and **y\_value**, iterated over the chart dimensions.

**Syntax:**

```
LINEST_DF ([{SetExpression}] [DISTINCT] [TOTAL [<fld{, fld}>]] y_value, x_value [, y0_const [, x0_const]])
```

**Return data type:** numeric

**Arguments:**

- **y\_value:** The expression or field containing the range of y-values to be measured.
- **x\_value:** The expression or field containing the range of x-values to be measured.
- **y0,x0:** An optional value y0 may be stated forcing the regression line to pass through the y-axis at a given point. By stating both y0 and x0 it is possible to force the regression line to pass through a single fixed coordinate.

*Unless both y0 and x0 are stated, the function requires at least two valid data-pairs to calculate. If y0 and x0 are stated, a single data pair will do.*

- **SetExpression**: By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT**: If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- **TOTAL**: If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Limitations:

The parameter of the aggregation function must not contain other aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

### LINEST\_F

This script function returns the aggregated F statistic ( $r^2/(1-r^2)$ ) of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

### Syntax:

```
LINEST_F (y-value, x-value[, y0 [, x0]])
```

**Return data type:** numeric

### Arguments:

LINEST\_F arguments

| Argument   | Description                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y_value    | The expression or field containing the range of y-values to be measured.                                                                                                                                                                                                                                                                                                                     |
| x_value    | The expression or field containing the range of x-values to be measured.                                                                                                                                                                                                                                                                                                                     |
| y(0), x(0) | An optional value y0 may be stated forcing the regression line to pass through the y-axis at a given point. By stating both y0 and x0 it is possible to force the regression line to pass through a single fixed coordinate.<br><br>Unless both y0 and x0 are stated, the function requires at least two valid data-pairs to calculate. If y0 and x0 are stated, a single data pair will do. |

### Limitations:

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

### LINEST\_F - chart function

**LINEST\_F()** returns the aggregated F statistic ( $r^2/(1-r^2)$ ) of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in the expressions given by **x\_value** and the **y\_value**, iterated over the chart dimensions.

### Syntax:

```
LINEST_F([{SetExpression}] [DISTINCT] [TOTAL [<fld{, fld}>]] y_value, x_value
[, y0_const [, x0_const]])
```

**Return data type:** numeric

### Arguments:

- **y\_value:** The expression or field containing the range of y-values to be measured.
- **x\_value:** The expression or field containing the range of x-values to be measured.
- **y0,x0:** An optional value y0 may be stated forcing the regression line to pass through the y-axis at a given point. By stating both y0 and x0 it is possible to force the regression line to pass through a single fixed coordinate.

*Unless both y0 and x0 are stated, the function requires at least two valid data-pairs to calculate. If y0 and x0 are stated, a single data pair will do.*

- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT:** If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Limitations:

The parameter of the aggregation function must not contain other aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

### LINEST\_M

**LINEST\_M()** returns the aggregated m value (slope) of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

#### Syntax:

```
LINEST_M (y-value, x-value[, y0 [, x0]])
```

**Return data type:** numeric

#### Arguments:

LINEST\_M arguments

| Argument   | Description                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y_value    | The expression or field containing the range of y-values to be measured.                                                                                                                                                                                                                                                                                                                     |
| x_value    | The expression or field containing the range of x-values to be measured.                                                                                                                                                                                                                                                                                                                     |
| y(0), x(0) | An optional value y0 may be stated forcing the regression line to pass through the y-axis at a given point. By stating both y0 and x0 it is possible to force the regression line to pass through a single fixed coordinate.<br><br>Unless both y0 and x0 are stated, the function requires at least two valid data-pairs to calculate. If y0 and x0 are stated, a single data pair will do. |

#### Limitations:

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

### LINEST\_M - chart function

**LINEST\_M()** returns the aggregated m value (slope) of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers given by the expressions **x\_value** and **y\_value**, iterated over the chart dimensions.

#### Syntax:

```
LINEST_M ([{SetExpression}] [DISTINCT] [TOTAL [<fld{, fld}>]] y_value, x_value
[, y0_const [, x0_const]])
```

**Return data type:** numeric

#### Arguments:

- **y\_value:** The expression or field containing the range of y-values to be measured.
- **x\_value:** The expression or field containing the range of x-values to be measured.

- $y_0, x_0$ : An optional value  $y_0$  may be stated forcing the regression line to pass through the y-axis at a given point. By stating both  $y_0$  and  $x_0$  it is possible to force the regression line to pass through a single fixed coordinate.

*Unless both  $y_0$  and  $x_0$  are stated, the function requires at least two valid data-pairs to calculate. If  $y_0$  and  $x_0$  are stated, a single data pair will do.*

- **SetExpression**: By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT**: If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- **TOTAL**: If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Limitations:

The parameter of the aggregation function must not contain other aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

### LINEST\_R2

**LINEST\_R2()** returns the aggregated  $r^2$  value (coefficient of determination) of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

### Syntax:

```
LINEST_R2 (y-value, x-value[, y0 [, x0]])
```

**Return data type:** numeric

### Arguments:

LINEST\_R2 arguments

| Argument | Description                                                              |
|----------|--------------------------------------------------------------------------|
| y_value  | The expression or field containing the range of y-values to be measured. |
| x_value  | The expression or field containing the range of x-values to be measured. |

| Argument   | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y(0), x(0) | <p>An optional value y0 may be stated forcing the regression line to pass through the y-axis at a given point. By stating both y0 and x0 it is possible to force the regression line to pass through a single fixed coordinate.</p> <p>Unless both y0 and x0 are stated, the function requires at least two valid data-pairs to calculate. If y0 and x0 are stated, a single data pair will do.</p> |

### Limitations:

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

### LINEST\_R2 - chart function

**LINEST\_R2()** returns the aggregated r2 value (coefficient of determination) of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers given by the expressions **x\_value** and **y\_value**, iterated over the chart dimensions.

### Syntax:

```
LINEST_R2 ([{SetExpression}] [DISTINCT] [TOTAL [<fld{, fld}>]] y_value, x_value[, y0_const[, x0_const]])
```

**Return data type:** numeric

### Arguments:

- **y\_value:** The expression or field containing the range of y-values to be measured.
- **x\_value:** The expression or field containing the range of x-values to be measured.
- **y0,x0:** An optional value y0 may be stated forcing the regression line to pass through the y-axis at a given point. By stating both y0 and x0 it is possible to force the regression line to pass through a single fixed coordinate.

*Unless both y0 and x0 are stated, the function requires at least two valid data-pairs to calculate. If y0 and x0 are stated, a single data pair will do.*

- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT:** If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

**Limitations:**

The parameter of the aggregation function must not contain other aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

**LINEST\_SEB**

**LINEST\_SEB()** returns the aggregated standard error of the b value of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

**Syntax:**

```
LINEST_SEB (y-value, x-value[, y0 [, x0]])
```

**Return data type:** numeric

**Arguments:**

LINEST\_SEB arguments

| Argument   | Description                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y_value    | The expression or field containing the range of y-values to be measured.                                                                                                                                                                                                                                                                                                                     |
| x_value    | The expression or field containing the range of x-values to be measured.                                                                                                                                                                                                                                                                                                                     |
| y(0), x(0) | An optional value y0 may be stated forcing the regression line to pass through the y-axis at a given point. By stating both y0 and x0 it is possible to force the regression line to pass through a single fixed coordinate.<br><br>Unless both y0 and x0 are stated, the function requires at least two valid data-pairs to calculate. If y0 and x0 are stated, a single data pair will do. |

**Limitations:**

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

**LINEST\_SEB - chart function**

**LINEST\_SEB()** returns the aggregated standard error of the b value of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers given by the expressions **x\_value** and **y\_value**, iterated over the chart dimensions.

**Syntax:**

```
LINEST_SEB ([{SetExpression}] [DISTINCT] [TOTAL [<fld{, fld}>]] y_value, x_value[, y0_const[, x0_const]])
```

**Return data type:** numeric

**Arguments:**

- **y\_value:** The expression or field containing the range of y-values to be measured.
- **x\_value:** The expression or field containing the range of x-values to be measured.
- **y0,x0:** An optional value y0 may be stated forcing the regression line to pass through the y-axis at a given point. By stating both y0 and x0 it is possible to force the regression line to pass through a single fixed coordinate.

*Unless both y0 and x0 are stated, the function requires at least two valid data-pairs to calculate. If y0 and x0 are stated, a single data pair will do.*

- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT:** If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

**Limitations:**

The parameter of the aggregation function must not contain other aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

### LINEST\_SEM

**LINEST\_SEM()** returns the aggregated standard error of the m value of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

**Syntax:**

```
LINEST_SEM (y-value, x-value[, y0 [, x0]])
```

**Return data type:** numeric

**Arguments:**

LINEST\_SEM arguments

| Argument   | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y_value    | The expression or field containing the range of y-values to be measured.                                                                                                                                                                                                                                                                                                                            |
| x_value    | The expression or field containing the range of x-values to be measured.                                                                                                                                                                                                                                                                                                                            |
| y(0), x(0) | <p>An optional value y0 may be stated forcing the regression line to pass through the y-axis at a given point. By stating both y0 and x0 it is possible to force the regression line to pass through a single fixed coordinate.</p> <p>Unless both y0 and x0 are stated, the function requires at least two valid data-pairs to calculate. If y0 and x0 are stated, a single data pair will do.</p> |

**Limitations:**

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

LINEST\_SEM - chart function

**LINEST\_SEM()** returns the aggregated standard error of the m value of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers given by the expressions **x\_value** and **y\_value**, iterated over the chart dimensions.

**Syntax:**

```
LINEST_SEM ([{SetExpression}] [DISTINCT] [TOTAL [<fld{, fld}>]] y_value, x_value[, y0_const[, x0_const]])
```

**Return data type:** numeric

**Arguments:**

- **y\_value:** The expression or field containing the range of y-values to be measured.
- **x\_value:** The expression or field containing the range of x-values to be measured.
- **y0,x0:** An optional value y0 may be stated forcing the regression line to pass through the y-axis at a given point. By stating both y0 and x0 it is possible to force the regression line to pass through a single fixed coordinate.

*Unless both y0 and x0 are stated, the function requires at least two valid data-pairs to calculate. If y0 and x0 are stated, a single data pair will do.*

- **SetExpression**: By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT**: If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- **TOTAL**: If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Limitations:

The parameter of the aggregation function must not contain other aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

### LINEST\_SEY

**LINEST\_SEY()** returns the aggregated standard error of the y estimate of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

### Syntax:

```
LINEST_SEY (y-value, x-value[, y0 [, x0]])
```

**Return data type:** numeric

### Arguments:

LINEST\_SEY arguments

| Argument   | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y_value    | The expression or field containing the range of y-values to be measured.                                                                                                                                                                                                                                                                                                                            |
| x_value    | The expression or field containing the range of x-values to be measured.                                                                                                                                                                                                                                                                                                                            |
| y(0), x(0) | <p>An optional value y0 may be stated forcing the regression line to pass through the y-axis at a given point. By stating both y0 and x0 it is possible to force the regression line to pass through a single fixed coordinate.</p> <p>Unless both y0 and x0 are stated, the function requires at least two valid data-pairs to calculate. If y0 and x0 are stated, a single data pair will do.</p> |

### Limitations:

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

### LINEST\_SEY - chart function

**LINEST\_SEY()** returns the aggregated standard error of the y estimate of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers given by the expressions **x\_value** and **y\_value**, iterated over the chart dimensions.

### Syntax:

```
LINEST_SEY ([{SetExpression}] [DISTINCT] [TOTAL [<fld{, fld}>]] y_value, x_value[, y0_const[, x0_const]])
```

**Return data type:** numeric

### Arguments:

- **y\_value:** The expression or field containing the range of y-values to be measured.
- **x\_value:** The expression or field containing the range of x-values to be measured.
- **y0,x0:** An optional value y0 may be stated forcing the regression line to pass through the y-axis at a given point. By stating both y0 and x0 it is possible to force the regression line to pass through a single fixed coordinate.

*Unless both y0 and x0 are stated, the function requires at least two valid data-pairs to calculate. If y0 and x0 are stated, a single data pair will do.*

- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT:** If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Limitations:

The parameter of the aggregation function must not contain other aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

### LINEST\_SSREG

**LINEST\_SSREG()** returns the aggregated regression sum of squares of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

#### Syntax:

```
LINEST_SSREG (y-value, x-value[, y0 [, x0]])
```

**Return data type:** numeric

#### Arguments:

LINEST\_SSREG arguments

| Argument   | Description                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y_value    | The expression or field containing the range of y-values to be measured.                                                                                                                                                                                                                                                                                                                     |
| x_value    | The expression or field containing the range of x-values to be measured.                                                                                                                                                                                                                                                                                                                     |
| y(0), x(0) | An optional value y0 may be stated forcing the regression line to pass through the y-axis at a given point. By stating both y0 and x0 it is possible to force the regression line to pass through a single fixed coordinate.<br><br>Unless both y0 and x0 are stated, the function requires at least two valid data-pairs to calculate. If y0 and x0 are stated, a single data pair will do. |

#### Limitations:

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

### LINEST\_SSREG - chart function

**LINEST\_SSREG()** returns the aggregated regression sum of squares of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers given by the expressions **x\_value** and **y\_value**, iterated over the chart dimensions.

#### Syntax:

```
LINEST_SSREG ([{SetExpression}] [DISTINCT] [TOTAL [<fld{, fld}>]] y_value, x_value[, y0_const[, x0_const]])
```

**Return data type:** numeric

#### Arguments:

- **y\_value:** The expression or field containing the range of y-values to be measured.
- **x\_value:** The expression or field containing the range of x-values to be measured.

- **y0,x0**: An optional value y0 may be stated forcing the regression line to pass through the y-axis at a given point. By stating both y0 and x0 it is possible to force the regression line to pass through a single fixed coordinate.

*Unless both y0 and x0 are stated, the function requires at least two valid data-pairs to calculate. If y0 and x0 are stated, a single data pair will do.*

- **SetExpression**: By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT**: If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- **TOTAL**: If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Limitations:

The parameter of the aggregation function must not contain other aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

### LINEST\_SSRESID

**LINEST\_SSRESID()** returns the aggregated residual sum of squares of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

### Syntax:

```
LINEST_SSRESID (y-value, x-value[, y0 [, x0]])
```

**Return data type:** numeric

### Arguments:

LINEST\_SSRESID arguments

| Argument | Description                                                              |
|----------|--------------------------------------------------------------------------|
| y_value  | The expression or field containing the range of y-values to be measured. |
| x_value  | The expression or field containing the range of x-values to be measured. |

| Argument   | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y(0), x(0) | <p>An optional value y0 may be stated forcing the regression line to pass through the y-axis at a given point. By stating both y0 and x0 it is possible to force the regression line to pass through a single fixed coordinate.</p> <p>Unless both y0 and x0 are stated, the function requires at least two valid data-pairs to calculate. If y0 and x0 are stated, a single data pair will do.</p> |

### Limitations:

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

### LINEST\_SSRESID - chart function

**LINEST\_SSRESID()** returns the aggregated residual sum of squares of a linear regression defined by the equation  $y=mx+b$  for a series of coordinates represented by paired numbers in the expressions given by **x\_value** and **y\_value**, iterated over the chart dimensions.

### Syntax:

```
LINEST_SSRESID ([{SetExpression}] [DISTINCT] [TOTAL [<fld{, fld}>]] y_value, x_value[, y0_const[, x0_const]])
```

**Return data type:** numeric

### Arguments:

- **y\_value:** The expression or field containing the range of y-values to be measured.
- **x\_value:** The expression or field containing the range of x-values to be measured.
- **y0,x0:** An optional value y0 may be stated forcing the regression line to pass through the y-axis at a given point. By stating both y0 and x0 it is possible to force the regression line to pass through a single fixed coordinate.

*Unless both y0 and x0 are stated, the function requires at least two valid data-pairs to calculate. If y0 and x0 are stated, a single data pair will do.*

- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT:** If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

---

## 9 Script syntax and chart functions

---

An optional value `y0` may be stated forcing the regression line to pass through the y-axis at a given point. By stating both `y0` and `x0` it is possible to force the regression line to pass through a single fixed coordinate.

### Limitations:

The parameter of the aggregation function must not contain other aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

### Median

**Median()** returns the aggregated median of the values in the expression over a number of records as defined by a **group by** clause.

### Syntax:

```
Median (expr)
```

**Return data type:** numeric

### Arguments:

Median arguments

| Argument          | Description                                                 |
|-------------------|-------------------------------------------------------------|
| <code>expr</code> | The expression or field containing the data to be measured. |

### Examples and results:

Add the example script to your app and run it. Then build a straight table with `Type` and `myMedian` as dimensions.

### Examples and results

| Example                                                                                                                                                                                                                                                                                            | Result                                                                                                                                                                               |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>Table1: crosstable LOAD recno() as ID, * inline [ Observation Comparison 35 2 40 27 12 38 15 31 21 1 14 19 46 1 10 34 28 3 48 1 16 2 30 3 32 2 48 1 31 2 22 1 12 3 39 29 19 37 25 2 ] (delimiter is ' ');  Median1: LOAD Type, Median(Value) as MyMedian Resident Table1 Group By Type;</pre> | <p>The results of the Median() calculation are:</p> <ul style="list-style-type: none"> <li>• Type is MyMedian</li> <li>• Comparison is 2.5</li> <li>• observation is 26.5</li> </ul> |

### Median - chart function

**Median()** returns the median value of the range of values aggregated in the expression iterated over the chart dimensions.

#### Syntax:

```
Median([SetExpression] [DISTINCT] [TOTAL [<fld{, fld}>]] expr)
```

**Return data type:** numeric

#### Arguments:

- **expr:** The expression or field containing the data to be measured.
- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT:** If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current

dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Limitations:

The parameter of the aggregation function must not contain other aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

### Examples:

Add the following example script to your app and run it.

```
Table1:
crosstable LOAD recno() as ID, * inline [
Observation|Comparison
35|2
40|27
12|38
15|31
21|1
14|19
46|1
10|34
28|3
48|1
16|2
30|3
32|2
48|1
31|2
22|1
12|3
39|29
19|37
25|2] (delimiter is '|');
```

Then build a straight table with `type` as dimension and `median(value)` as measure. `Totals` should be enabled in the properties of the table.

### Result:

The median values for:

- Totals is 19
- Comparison is 2.5
- Observation is 26.5

### MutualInfo - chart function

**MutualInfo** calculates the mutual information (MI) between two fields or between aggregated values in **Aggr()**.

**MutualInfo** enables different kinds of MI analysis:

- Pair-wise MI: Calculate the MI between a driver field and a target field.
- Driver breakdown by value: The MI is calculated between individual field values in the driver and target fields.
- Feature selection: Use **MutualInfo** in a grid chart to create a matrix where all fields are compared to each other based on MI.

**MutualInfo** returns the aggregated mutual information for two data sets. Mutual information is a measure of the relationship between the datasets and is aggregated for (x,y) pair values iterated over the chart dimensions. Mutual information is measured between 0 and 1. **MutualInfo** is defined by the selection or the set expression.

When calculating mutual information, associations affect the correspondence between and the frequency of values from fields that are from different tables.

Returned values for the same target and driver may vary slightly. This is due to each **MutualInfo** call operates on a randomly selected sample and the inherent randomness of the **MutualInfo** algorithm.

**MutualInfo** can be applied to the **Aggr()** function.

### Syntax:

```
MutualInfo ({SetExpression}) [DISTINCT] [TOTAL] target, driver , datatype [,
breakdownbyvalue [, samplesize]])
```

**Return data type:** numeric

### Arguments:

#### Arguments

| Argument       | Description                                                                                                                                                                                                                                                      |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| target, driver | The expressions or fields containing the two sample sets for which the mutual information to be measured.                                                                                                                                                        |
| datatype       | The data types contained in the target and driver,<br><br>1 or 'dd' for discrete:discrete<br><br>2 or 'cc' for continuous:continuous<br><br>3 or 'cd' for continuous:discrete<br><br>4 or 'dc' for discrete:continuous<br><br>Data types are not case sensitive. |

| Argument         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| breakdownbyvalue | <p>A static value corresponding to a value in the driver. If supplied, the calculation will calculate the MI contribution for that value. You can use <b>ValueList()</b> or <b>ValueLoop()</b>. If <b>Null()</b> is added, the calculation will calculate the overall MI for all values in the driver.</p> <p>Breaking down by value requires the driver contain discrete data.</p>                                                                           |
| samplesize       | <p>The number of values to sample from the target and driver. Sampling is random. <b>MutualInfo</b> requires a minimum sample size of 80. By default, <b>MutualInfo</b> only samples up to 10,000 data-pairs as <b>MutualInfo</b> can be resource intensive. You can specify greater numbers of data-pairs in the sample size. If <b>MutualInfo</b> times out, reduce the sample size.</p>                                                                    |
| SetExpression    | <p>By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.</p>                                                                                                                                                                                                                                                              |
| DISTINCT         | <p>If the word <b>DISTINCT</b> occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.</p>                                                                                                                                                                                                                                                                                                  |
| TOTAL            | <p>If the word <b>TOTAL</b> occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The <b>TOTAL</b> qualifier may be followed by a list of one or more field names within angle brackets &lt;fld&gt;. These field names should be a subset of the chart dimension variables.</p> |

### Limitations:

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

### Examples and results:

Add the example script to your app and run it. Then add the fields listed in the results column to a sheet in your app to see the result.

#### Function examples

| Example                                | Result                                                                                                                                                                                                      |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>mutualinfo (Age, Salary, 1)</pre> | <p>For a table including the dimension <code>Employee name</code> and the measure <code>mutualinfo (Age, salary, 1)</code>, the result is 0.99820986. The result is only displayed for the totals cell.</p> |

| Example                                                          | Result                                                                                                                                                                                                                                                                            |
|------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mutualinfo<br>(TOTAL Age,<br>Salary, 1,<br>null(), 81)           | If you create a filter pane with the dimension Gender, and make selections from it, you see the result 0.99805677 when Female is selected and 0.99847373 if Male is selected. This is because the selection excludes all results that do not belong to the other value of Gender. |
| mutualinfo<br>(TOTAL Age,<br>Gender, 1,<br>ValueLoop<br>(25,35)) | 0.68196996. Selecting any value from Gender will change this to 0.                                                                                                                                                                                                                |
| mutualinfo({1}<br>TOTAL Age,<br>Salary, 1,<br>null())            | 0.99820986. This is independent of selections. The set expression {1} disregards all selections and dimensions.                                                                                                                                                                   |

```

### Skew

**Skew()** returns the skewness of expression over a number of records as defined by a **group by** clause.

### Syntax:

```
Skew([distinct] expr)
```

**Return data type:** numeric

### Arguments:

#### Skew arguments

| Argument | Description                                                                                   |
|----------|-----------------------------------------------------------------------------------------------|
| expr     | The expression or field containing the data to be measured.                                   |
| DISTINCT | If the word <b>distinct</b> occurs before the expression, all duplicates will be disregarded. |

### Examples and results:

Add the example script to your app and run it. Then build a straight table with `Type` and `MySkew` as dimensions.

#### Examples and results

| Example                                                                                                                                                                                                                                                                                      | Result                                                                                                                                                                                                                |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>Table1: crosstable LOAD recno() as ID, * inline [ Observation Comparison 35 2 40 27 12 38 15 31 21 1 14 19 46 1 10 34 28 3 48 1 16 2 30 3 32 2 48 1 31 2 22 1 12 3 39 29 19 37 25 2 ] (delimiter is ' ');  Skew1: LOAD Type, Skew(Value) as MySkew Resident Table1 Group By Type;</pre> | <p>The results of the Skew() calculation in the data load script are:</p> <ul style="list-style-type: none"> <li>• Type is MySkew</li> <li>• Comparison is 0.86414768</li> <li>• Observation is 0.32625351</li> </ul> |

### Skew - chart function

**Skew()** returns the aggregated skewness of the expression or field iterated over the chart dimensions.

#### Syntax:

```
Skew ([{SetExpression}] [DISTINCT] [TOTAL [<fld{, fld}>]] expr)
```

**Return data type:** numeric

#### Arguments:

- **expr:** The expression or field containing the data to be measured.
- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT:** If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

#### Limitations:

The parameter of the aggregation function must not contain other aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

#### Examples:

Add the example script to your app and run it.

```
Table1:
crosstable LOAD recno() as ID, * inline [
Observation|Comparison
35|2
40|27
12|38
15|31
21|1
14|19
46|1
10|34
28|3
48|1
16|2
30|3
32|2
48|1
31|2
22|1
```

```
12|3
39|29
19|37
25|2] (delimiter is '|');
```

Then build a straight table with `type` as dimension and `skew(value)` as measure. `totals` should be enabled in the properties of the table.

### Result:

The results of the `Skew(Value)` calculation are:

- `total` is 0.23522195
- `comparison` is 0.86414768
- `observation` is 0.32625351

### Stdev

**Stdev()** returns the standard deviation of the values given by the expression over a number of records as defined by a **group by** clause.

### Syntax:

```
Stdev([distinct] expr)
```

**Return data type:** numeric

### Arguments:

Stdev arguments

| Argument              | Description                                                                                   |
|-----------------------|-----------------------------------------------------------------------------------------------|
| <code>expr</code>     | The expression or field containing the data to be measured.                                   |
| <code>distinct</code> | If the word <b>distinct</b> occurs before the expression, all duplicates will be disregarded. |

### Examples and results:

Add the example script to your app and run it. Then build a straight table with `type` and `mystdev` as dimensions.

### Examples and results

| Example                                                                                                                                                                                                                                                                                         | Result                                                                                                                                                                                       |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>Table1: crosstable LOAD recno() as ID, * inline [ Observation Comparison 35 2 40 27 12 38 15 31 21 1 14 19 46 1 10 34 28 3 48 1 16 2 30 3 32 2 48 1 31 2 22 1 12 3 39 29 19 37 25 2 ] (delimiter is ' ');  Stdev1: LOAD Type, stdev(Value) as MyStdev Resident Table1 Group By Type;</pre> | <p>The results of the Stdev() calculation are:</p> <ul style="list-style-type: none"> <li>• Type is MyStdev</li> <li>• Comparison is 14.61245</li> <li>• Observation is 12.507997</li> </ul> |

### Stdev - chart function

**Stdev()** finds the standard deviation of the range of data aggregated in the expression or field iterated over the chart dimensions.

#### Syntax:

```
Stdev ([{SetExpression}] [DISTINCT] [TOTAL [<fld{, fld}>]] expr)
```

**Return data type:** numeric

#### Arguments:

- **expr:** The expression or field containing the data to be measured.
- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT:** If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current

dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Limitations:

The parameter of the aggregation function must not contain other aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

### Examples:

Add the example script to your app and run it.

```
Table1:
crosstable LOAD recno() as ID, * inline [
Observation|Comparison
35|2
40|27
12|38
15|31
21|1
14|19
46|1
10|34
28|3
48|1
16|2
30|3
32|2
48|1
31|2
22|1
12|3
39|29
19|37
25|2] (delimiter is '|');
```

Then build a straight table with `Type` as dimension and `stdev(Value)` as measure. `TOTALs` should be enabled in the properties of the table.

### Result:

The results of the `Stdev(Value)` calculation are:

- Total is 15.47529
- comparison is 14.61245
- observation is 12.507997

### Sterr

**Sterr()** returns the aggregated standard error ( $stdev/\sqrt{n}$ ) for a series of values represented by the expression iterated over a number of records as defined by a **group by** clause.

**Syntax:**

```
Sterr ([distinct] expr)
```

**Return data type:** numeric

**Arguments:**

Sterr arguments

| Argument        | Description                                                                                   |
|-----------------|-----------------------------------------------------------------------------------------------|
| <i>expr</i>     | The expression or field containing the data to be measured.                                   |
| <i>distinct</i> | If the word <b>distinct</b> occurs before the expression, all duplicates will be disregarded. |

**Limitations:**

Text values, NULL values and missing values are disregarded.

**Examples and results:**

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

### Examples and results

| Example                                                                                                                                                                                                                                                                                         | Result                                                                                                                                                                                                                           |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>Table1: crosstable LOAD recno() as ID, * inline [ Observation Comparison 35 2 40 27 12 38 15 31 21 1 14 19 46 1 10 34 28 3 48 1 16 2 30 3 32 2 48 1 31 2 22 1 12 3 39 29 19 37 25 2 ] (delimiter is ' ');  Sterr1: LOAD Type, Sterr(Value) as MySterr Resident Table1 Group By Type;</pre> | <p>In a table with the dimensions <code>Type</code> and <code>MySterr</code>, the results of the <code>Sterr()</code> calculation in the load script are:</p> <pre>Type MySterr Comparison 3.2674431 Observation 2.7968733</pre> |

### Sterr - chart function

**Sterr()** finds the value of the standard error of the mean, ( $\text{stdev}/\sqrt{n}$ ), for the series of values aggregated in the expression iterated over the chart dimensions.

#### Syntax:

```
Sterr ([{SetExpression}] [DISTINCT] [TOTAL [<fld{, fld}>]] expr)
```

**Return data type:** numeric

#### Arguments:

- `expr`: The expression or field containing the data to be measured.
- `SetExpression`: By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- `DISTINCT`: If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.

- **TOTAL**: If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Limitations:

The parameter of the aggregation function must not contain other aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

Text values, NULL values and missing values are disregarded.

### Examples:

Add the example script to your app and run it, using `sterr(value)`.

```
Table1:
crosstable LOAD recno() as ID, * inline [
observation|Comparison
35|2
40|27
12|38
15|31
21|1
14|19
46|1
10|34
28|3
48|1
16|2
30|3
32|2
48|1
31|2
22|1
12|3
39|29
19|37
25|2] (delimiter is '|');
```

Then build a straight table with `type` as dimension and `sterr(value)` as measure. `TOTALs` should be enabled in the properties of the table.

### Result:

The results of the `Sterr(Value)` calculation are:

- `Total` is 2.4468583
- `Comparison` is 3.2674431
- `observation` is 2.7968733

### STEYX

**STEYX()** returns the aggregated standard error of the predicted y-value for each x-value in the regression for a series of coordinates represented by paired numbers in x-expression and y-expression iterated over a number of records as defined by a **group by** clause.

#### Syntax:

```
STEYX (y-value, x-value)
```

**Return data type:** numeric

#### Arguments:

STEYX arguments

| Argument | Description                                                              |
|----------|--------------------------------------------------------------------------|
| y_value  | The expression or field containing the range of y-values to be measured. |
| x_value  | The expression or field containing the range of x-values to be measured. |

#### Limitations:

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

#### Examples and results:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

### Examples and results

| Example                                                                                                                                                                                                                                                                                 | Result                                                                                                                                         |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>Trend: Load *, 1 as Grp; LOAD * inline [ Month KnownY KnownX Jan 2 6 Feb 3 5 Mar 9 11 Apr 6 7 May 8 5 Jun 7 4 Jul 5 5 Aug 10 8 Sep 9 10 Oct 12 14 Nov 15 17 Dec 14 16 ] (delimiter is ' ');  STEYX1: LOAD Grp, STEYX(KnownY, KnownX) as MySTEYX Resident Trend Group By Grp;</pre> | <p>In a table with the dimension <code>MySTEYX</code>, the result of the <code>STEYX()</code> calculation in the load script is 2.0714764.</p> |

### STEYX - chart function

**STEYX()** returns the aggregated standard error when predicting y-values for each x-value in a linear regression given by a series of coordinates represented by paired numbers in the expressions given by **y\_value** and **x\_value**.

#### Syntax:

```
STEYX([SetExpression] [DISTINCT] [TOTAL [<fld{, fld}>]] y_value, x_value)
```

**Return data type:** numeric

#### Arguments:

- **y\_value**: The expression or field containing the range of known y-values to be measured.
- **x\_value**: The expression or field containing the range of known x-values to be measured.
- **SetExpression**: By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT**: If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- **TOTAL**: If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed

by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Limitations:

The parameter of the aggregation function must not contain other aggregation functions, unless these inner aggregations contain the **TOTAL** qualifier. For more advanced nested aggregations, use the advanced function **Aggr**, in combination with a specified dimension.

Text values, NULL values and missing values in any or both pieces of a data-pair result in the entire data-pair being disregarded.

### Examples:

Add the example script to your app and run it.

```
Trend:
LOAD * inline [
Month|KnownY|KnownX
Jan|2|6
Feb|3|5
Mar|9|11
Apr|6|7
May|8|5
Jun|7|4
Jul|5|5
Aug|10|8
Sep|9|10
Oct|12|14
Nov|15|17
Dec|14|16
] (delimiter is '|');
```

Then build a straight table with `KnownY` and `KnownX` as dimension and `Steyx(KnownY, KnownX)` as measure. `TOTALs` should be enabled in the properties of the table.

### Result:

The result of the `STEYX(KnownY, KnownX)` calculation is 2.071 (If number formatting is set to 3 decimal places.)

### An example of how to use linest functions

The linest functions are used to find values associated with linear regression analysis. This section describes how to build charts using sample data to find the values of the linest functions available in QlikView. The linest functions can be used in the load script and in chart expressions.

Please refer to the individual linest chart function and script function topics for descriptions of syntax and arguments.

### Loading the sample data

Do the following:

1. Create a new document.
2. Select **Edit Script** in the toolbar and enter the following to the script:

```
T1:
LOAD *, 1 as Grp;
LOAD * inline [
X |Y
1| 0
2|1
3|3
4| 8
5| 14
6| 20
7| 0
8| 50
9| 25
10| 60
11| 38
12| 19
13| 26
14| 143
15| 98
16| 27
17| 59
18| 78
19| 158
20| 279] (delimiter is '|');
R1:
LOAD
Grp,
linest_B(Y,X) as Linest_B,
linest_DF(Y,X) as Linest_DF,
linest_F(Y,X) as Linest_F,
linest_M(Y,X) as Linest_M,
linest_R2(Y,X) as Linest_R2,
linest_SEB(Y,X,1,1) as Linest_SEB,
linest_SEM(Y,X) as Linest_SEM,
linest_SEY(Y,X) as Linest_SEY,
linest_SSREG(Y,X) as Linest_SSREG,
linest_SSRESID(Y,X) as Linest_SSRESID
resident T1 group by Grp;
```

3. Save the script and click **Reload** to load the data.

### Displaying the results from the script calculations

Do the following:

1. Add a table box on the sheet and select the following fields to be displayed:
  - Linest\_B
  - Linest\_DF
  - Linest\_F
  - Linest\_M
  - Linest\_R2
  - Linest\_SEB
  - Linest\_SEM

- Linest\_SEY
- Linest\_SSREG
- Linest\_SSRESID

The table containing the results of the linest calculations made in the load script should look like this:

Example results (first 5 entries)

| Linest_B | Linest_DF | Linest_F | Linest_M | Linest_R2 |
|----------|-----------|----------|----------|-----------|

Example results (last 5 entries)

| Linest_SEB | Linest_SEM | Linest_SEY | Linest_SSREG | Linest_SSRESID |
|------------|------------|------------|--------------|----------------|
| 22.607     | 1.887      | 48.666     | 49235.014    | 42631.186      |

### Creating the linest chart function charts

Do the following:

1. Create a new line chart by going to **Object > New Sheet Object > Chart...**:
  - In the **Dimensions** window, add X as a dimension.
  - In the **Expression** window, add Sum(Y) as a measure.
  - In the **Presentation** window, deselect **Suppress Zero-Values**.

A line chart is created that represents the graph of X plotted against Y, from which the linest functions are calculated.

2. For the expression Sum(Y), enable the linear Trend Line feature and check Show Equation. This will show QlikView's built-in line of best fit with the linear regression function described.
3. Compute the linear regression function using the linest\_b and linest\_m functions by adding a second expression, defined as:  

$$\$(=LINEST\_M(Y,X))*ONLY(X)+\$(=LINEST\_B(Y,X))$$

4. Add a straight table on the sheet and add the following as a calculated dimension:  
`valueList('Linest_b', 'Linest_df', 'Linest_f', 'Linest_m', 'Linest_r2', 'Linest_SEB', 'Linest_SEM', 'Linest_SEY', 'Linest_SSREG', 'Linest_SSRESID')`

This uses the synthetic dimensions function to create labels for the dimensions with the names of the linest functions. You can change the label to **Linest functions** to save space.

5. Add the following expression to the table as a measure:

```
Pick(Match(ValueList('Linest_b', 'Linest_df', 'Linest_f', 'Linest_m', 'Linest_r2', 'Linest_SEB', 'Linest_SEM', 'Linest_SEY', 'Linest_SSREG', 'Linest_SSRESID'), 'Linest_b', 'Linest_df', 'Linest_f', 'Linest_m', 'Linest_r2', 'Linest_SEB', 'Linest_SEM', 'Linest_SEY', 'Linest_SSREG', 'Linest_SSRESID'), Linest_b(Y,X), Linest_df(Y,X), Linest_f(Y,X), Linest_m(Y,X), Linest_r2(Y,X), Linest_SEB(Y,X,1,1), Linest_SEM(Y,X), Linest_SEY(Y,X), Linest_SSREG(Y,X), Linest_SSRESID(Y,X))
```

This displays the value of the result of each linest function against the corresponding name in the synthetic dimension. The result of `Linest_b(Y,X)` is displayed next to **linest\_b**, and so on.

Example output in table form

| Linest functions | Linest function results |
|------------------|-------------------------|
| Linest_b         | -35.047                 |
| Linest_df        | 18                      |
| Linest_f         | 20.788                  |
| Linest_m         | 8.605                   |
| Linest_r2        | 0.536                   |
| Linest_SEB       | 22.607                  |
| Linest_SEM       | 1.887                   |
| Linest_SEY       | 48.666                  |
| Linest_SSREG     | 49235.014               |
| Linest_SSRESID   | 42631.186               |

### Statistical test functions

This section describes functions for statistical tests, which are divided into three categories. The functions can be used in both the load script and chart expressions, but the syntax differs.

#### Chi-2 test functions

Generally used in the study of qualitative variables. One can compare observed frequencies in a one-way frequency table with expected frequencies, or study the connection between two variables in a contingency table.

#### T-test functions

T-test functions are used for statistical examination of two population means. A two-sample t-test examines whether two samples are different and is commonly used when two normal distributions have unknown variances and when an experiment uses a small sample size.

#### Z-test functions

A statistical examination of two population means. A two sample z-test examines whether two samples are different and is commonly used when two normal distributions have known variances and when an experiment uses a large sample size.

#### Chi2-test functions

Generally used in the study of qualitative variables. One can compare observed frequencies in a one-way frequency table with expected frequencies, or study the connection between two variables in a contingency table.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

Chi2Test\_chi2

**Chi2Test\_chi2()** returns the aggregated chi<sup>2</sup>-test value for one or two series of values.

```
Chi2Test_chi2(col, row, actual_value[, expected_value])
```

Chi2Test\_df

**Chi2Test\_df()** returns the aggregated chi<sup>2</sup>-test df value (degrees of freedom) for one or two series of values.

```
Chi2Test_df(col, row, actual_value[, expected_value])
```

Chi2Test\_p

**Chi2Test\_p()** returns the aggregated chi<sup>2</sup>-test p value (significance) for one or two series of values.

```
Chi2Test_p - chart function(col, row, actual_value[, expected_value])
```

Chi2Test\_chi2

**Chi2Test\_chi2()** returns the aggregated chi<sup>2</sup>-test value for one or two series of values.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

*All QlikView chi<sup>2</sup>-test functions have the same arguments.*

### Syntax:

```
Chi2Test_chi2(col, row, actual_value[, expected_value])
```

**Return data type:** numeric

### Arguments:

- **col, row:** The specified column and row in the matrix of values being tested.
- **actual\_value:** The observed value of the data at the specified **col** and **row**.
- **expected\_value:** The expected value for the distribution at the specified **col** and **row**.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
Chi2Test_chi2(Grp, Grade, Count)
Chi2Test_chi2(Gender, Description, Observed, Expected)
```

### Chi2Test\_df

**Chi2Test\_df()** returns the aggregated chi<sup>2</sup>-test df value (degrees of freedom) for one or two series of values.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

*All QlikView chi<sup>2</sup>-test functions have the same arguments.*

### Syntax:

```
Chi2Test_df(col, row, actual_value[, expected_value])
```

**Return data type:** numeric

### Arguments:

- **col, row:** The specified column and row in the matrix of values being tested.
- **actual\_value:** The observed value of the data at the specified **col** and **row**.
- **expected\_value:** The expected value for the distribution at the specified **col** and **row**.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
Chi2Test_df(Grp, Grade, Count)
Chi2Test_df(Gender, Description, Observed, Expected)
```

### Chi2Test\_p - chart function

**Chi2Test\_p()** returns the aggregated chi<sup>2</sup>-test p value (significance) for one or two series of values. The test can be done either on the values in **actual\_value**, testing for variations within the specified **col** and **row** matrix, or by comparing values in **actual\_value** with corresponding values in **expected\_value**, if specified.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

*All QlikView chi<sup>2</sup>-test functions have the same arguments.*

### Syntax:

```
Chi2Test_p(col, row, actual_value[, expected_value])
```

**Return data type:** numeric

**Arguments:**

- `col, row`: The specified column and row in the matrix of values being tested.
- `actual_value`: The observed value of the data at the specified **col** and **row**.
- `expected_value`: The expected value for the distribution at the specified **col** and **row**.

**Limitations:**

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

**Examples:**

```
Chi2Test_p(grp, Grade, Count)
Chi2Test_p(Gender, Description, Observed, Expected)
```

### T-test functions

T-test functions are used for statistical examination of two population means. A two-sample t-test examines whether two samples are different and is commonly used when two normal distributions have unknown variances and when an experiment uses a small sample size.

In the following sections, the t-test statistical test functions are grouped according to the sample student test that applies to each type of function.

*Loading the sample data (page 1200)*

### Two independent samples t-tests

The following functions apply to two independent samples student's t-tests:

`ttest_conf`

**TTest\_conf** returns the aggregated t-test confidence interval value for two independent samples.

```
TTest_conf (grp, value [, sig[, eq_var]])
```

`ttest_df`

**TTest\_df()** returns the aggregated student's t-test value (degrees of freedom) for two independent series of values.

```
TTest_df (grp, value [, eq_var])
```

`ttest_dif`

**TTest\_dif()** is a numeric function that returns the aggregated student's t-test mean difference for two independent series of values.

```
TTest_dif (grp, value)
```

ttest\_lower

**TTest\_lower()** returns the aggregated value for the lower end of the confidence interval for two independent series of values.

```
TTest_lower (grp, value [, sig[, eq_var]])
```

ttest\_sig

**TTest\_sig()** returns the aggregated student's t-test 2-tailed level of significance for two independent series of values.

```
TTest_sig (grp, value [, eq_var])
```

ttest\_sterr

**TTest\_sterr()** returns the aggregated student's t-test standard error of the mean difference for two independent series of values.

```
TTest_sterr (grp, value [, eq_var])
```

ttest\_t

**TTest\_t()** returns the aggregated t value for two independent series of values.

```
TTest_t (grp, value [, eq_var])
```

ttest\_upper

**TTest\_upper()** returns the aggregated value for the upper end of the confidence interval for two independent series of values.

```
TTest_upper (grp, value [, sig [, eq_var]])
```

### Two independent weighted samples t-tests

The following functions to two independent samples student's t-tests where the input data series is given in weighted two-column format:

ttestw\_conf

**TTestw\_conf()** returns the aggregated t value for two independent series of values.

```
TTestw_conf (weight, grp, value [, sig[, eq_var]])
```

ttestw\_df

**TTestw\_df()** returns the aggregated student's t-test df value (degrees of freedom) for two independent series of values.

```
TTestw_df (weight, grp, value [, eq_var])
```

ttestw\_dif

**TTestw\_dif()** returns the aggregated student's t-test mean difference for two independent series of values.

```
TTestw_dif (weight, grp, value)
```

ttestw\_lower

**TTestw\_lower()** returns the aggregated value for the lower end of the confidence interval for two independent series of values.

```
TTestw_lower (weight, grp, value [, sig[, eq_var]])
```

ttestw\_sig

**TTestw\_sig()** returns the aggregated student's t-test 2-tailed level of significance for two independent series of values.

```
TTestw_sig (weight, grp, value [, eq_var])
```

ttestw\_sterr

**TTestw\_sterr()** returns the aggregated student's t-test standard error of the mean difference for two independent series of values.

```
TTestw_sterr (weight, grp, value [, eq_var])
```

ttestw\_t

**TTestw\_t()** returns the aggregated t value for two independent series of values.

```
TTestw_t (weight, grp, value [, eq_var])
```

ttestw\_upper

**TTestw\_upper()** returns the aggregated value for the upper end of the confidence interval for two independent series of values.

```
TTestw_upper (weight, grp, value [, sig [, eq_var]])
```

### One sample t-tests

The following functions apply to one-sample student's t-tests:

ttest1\_conf

**TTest1\_conf()** returns the aggregated confidence interval value for a series of values.

```
TTest1_conf (value [, sig])
```

ttest1\_df

**TTest1\_df()** returns the aggregated student's t-test df value (degrees of freedom) for a series of values.

```
TTest1_df (value)
```

ttest1\_dif

**TTest1\_dif()** returns the aggregated student's t-test mean difference for a series of values.

```
TTest1_dif (value)
```

ttest1\_lower

**TTest1\_lower()** returns the aggregated value for the lower end of the confidence interval for a series of values.

```
TTest1_lower (value [, sig])
```

ttest1\_sig

**TTest1\_sig()** returns the aggregated student's t-test 2-tailed level of significance for a series of values.

```
TTest1_sig (value)
```

ttest1\_sterr

**TTest1\_sterr()** returns the aggregated student's t-test standard error of the mean difference for a series of values.

```
TTest1_sterr (value)
```

ttest1\_t

**TTest1\_t()** returns the aggregated t value for a series of values.

```
TTest1_t (value)
```

ttest1\_upper

**TTest1\_upper()** returns the aggregated value for the upper end of the confidence interval for a series of values.

```
TTest1_upper (value [, sig])
```

### One weighted sample t-tests

The following functions apply to one-sample student's t-tests where the input data series is given in weighted two-column format:

ttest1w\_conf

**TTest1w\_conf()** is a **numeric** function that returns the aggregated confidence interval value for a series of values.

```
TTest1w_conf (weight, value [, sig])
```

ttest1w\_df

**TTest1w\_df()** returns the aggregated student's t-test df value (degrees of freedom) for a series of values.

```
TTest1w_df (weight, value)
```

ttest1w\_dif

**TTest1w\_dif()** returns the aggregated student's t-test mean difference for a series of values.

```
TTest1w_dif (weight, value)
```

ttest1w\_lower

**TTest1w\_lower()** returns the aggregated value for the lower end of the confidence interval for a series of values.

```
TTest1w_lower (weight, value [, sig])
```

ttest1w\_sig

**TTest1w\_sig()** returns the aggregated student's t-test 2-tailed level of significance for a series of values.

```
TTest1w_sig (weight, value)
```

ttest1w\_sterr

**TTest1w\_sterr()** returns the aggregated student's t-test standard error of the mean difference for a series of values.

```
TTest1w_sterr (weight, value)
```

ttest1w\_t

**TTest1w\_t()** returns the aggregated t value for a series of values.

```
TTest1w_t (weight, value)
```

ttest1w\_upper

**TTest1w\_upper()** returns the aggregated value for the upper end of the confidence interval for a series of values.

```
TTest1w_upper (weight, value [, sig])
```

**TTest\_conf**

**TTest\_conf** returns the aggregated t-test confidence interval value for two independent samples.

This function applies to independent samples student's t-tests.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

**Syntax:**

```
TTest_conf (grp, value [, sig [, eq_var]])
```

**Return data type:** numeric

**Arguments:**

- **value:** The sample values to be evaluated. The sample values must be logically grouped as specified by exactly two values in **group**. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **grp:** The field containing the names of each of the two sample groups. If a field name for the group is not provided in the load script, the field will automatically be given the name **Type**.
- **sig:** The two-tailed level of significance can be specified in **sig**. If omitted, **sig** is set to 0.025, resulting in a 95% confidence interval.
- **eq\_var:** If **eq\_var** is specified as False (0), separate variances of the two samples will be assumed. If **eq\_var** is specified as True (1), equal variances between the samples will be assumed.

**Limitations:**

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
TTest_conf(Group, Value)
TTest_conf(Group, Value, Sig, false)
```

### TTest\_df

**TTest\_df()** returns the aggregated student's t-test value (degrees of freedom) for two independent series of values.

This function applies to independent samples student's t-tests.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
TTest_df (grp, value [, eq_var])
```

**Return data type:** numeric

### Arguments:

- **value:** The sample values to be evaluated. The sample values must be logically grouped as specified by exactly two values in **group**. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **grp:** The field containing the names of each of the two sample groups. If a field name for the group is not provided in the load script, the field will automatically be given the name **Type**.
- **eq\_var:** If **eq\_var** is specified as False (0), separate variances of the two samples will be assumed. If **eq\_var** is specified as True (1), equal variances between the samples will be assumed.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
TTest_df(Group, Value)
TTest_df(Group, Value, false)
```

### TTest\_dif

**TTest\_dif()** is a numeric function that returns the aggregated student's t-test mean difference for two independent series of values.

This function applies to independent samples student's t-tests.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
TTest_dif (grp, value [, eq_var])
```

**Return data type:** numeric

### Arguments:

- **value:** The sample values to be evaluated. The sample values must be logically grouped as specified by exactly two values in **group**. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **grp:** The field containing the names of each of the two sample groups. If a field name for the group is not provided in the load script, the field will automatically be given the name **Type**.
- **eq\_var:** If **eq\_var** is specified as False (0), separate variances of the two samples will be assumed. If **eq\_var** is specified as True (1), equal variances between the samples will be assumed.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
TTest_dif(Group, Value)
TTest_dif(Group, Value, false)
```

### TTest\_lower

**TTest\_lower()** returns the aggregated value for the lower end of the confidence interval for two independent series of values.

This function applies to independent samples student's t-tests.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
TTest_lower (grp, value [, sig [, eq_var]])
```

**Return data type:** numeric

### Arguments:

- **value:** The sample values to be evaluated. The sample values must be logically grouped as specified by exactly two values in **group**. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **grp:** The field containing the names of each of the two sample groups. If a field name for the group is not provided in the load script, the field will automatically be given the name **Type**.

- **sig**: The two-tailed level of significance can be specified in **sig**. If omitted, **sig** is set to 0.025, resulting in a 95% confidence interval.
- **eq\_var**: If **eq\_var** is specified as False (0), separate variances of the two samples will be assumed. If **eq\_var** is specified as True (1), equal variances between the samples will be assumed.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
TTest_lower(Group, value)
TTest_lower(Group, value, sig, false)
```

### TTest\_sig

**TTest\_sig()** returns the aggregated student's t-test 2-tailed level of significance for two independent series of values.

This function applies to independent samples student's t-tests.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
TTest_sig (grp, value [, eq_var])
```

**Return data type:** numeric

### Arguments:

- **value**: The sample values to be evaluated. The sample values must be logically grouped as specified by exactly two values in **group**. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **grp**: The field containing the names of each of the two sample groups. If a field name for the group is not provided in the load script, the field will automatically be given the name **Type**.
- **eq\_var**: If **eq\_var** is specified as False (0), separate variances of the two samples will be assumed. If **eq\_var** is specified as True (1), equal variances between the samples will be assumed.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
TTest_sig(Group, value)
TTest_sig(Group, value, false)
```

### TTest\_sterr

**TTest\_sterr()** returns the aggregated student's t-test standard error of the mean difference for two independent series of values.

This function applies to independent samples student's t-tests.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

#### Syntax:

```
TTest_sterr (grp, value [, eq_var])
```

**Return data type:** numeric

#### Arguments:

- **value:** The sample values to be evaluated. The sample values must be logically grouped as specified by exactly two values in **group**. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **grp:** The field containing the names of each of the two sample groups. If a field name for the group is not provided in the load script, the field will automatically be given the name **Type**.
- **eq\_var:** If **eq\_var** is specified as False (0), separate variances of the two samples will be assumed. If **eq\_var** is specified as True (1), equal variances between the samples will be assumed.

#### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

#### Examples:

```
TTest_sterr(Group, value)
TTest_sterr(Group, value, false)
```

### TTest\_t

**TTest\_t()** returns the aggregated t value for two independent series of values.

This function applies to independent samples student's t-tests.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

#### Syntax:

```
TTest_t(grp, value[, eq_var])
```

**Return data type:** numeric

**Arguments:**

- **value:** The sample values to be evaluated. The sample values must be logically grouped as specified by exactly two values in **group**. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **grp:** The field containing the names of each of the two sample groups. If a field name for the group is not provided in the load script, the field will automatically be given the name **Type**.
- **eq\_var:** If **eq\_var** is specified as False (0), separate variances of the two samples will be assumed. If **eq\_var** is specified as True (1), equal variances between the samples will be assumed.

**Limitations:**

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

**Example:**

```
TTest_t(Group, Value, false)
```

**TTest\_upper**

**TTest\_upper()** returns the aggregated value for the upper end of the confidence interval for two independent series of values.

This function applies to independent samples student's t-tests.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

**Syntax:**

```
TTest_upper (grp, value [, sig [, eq_var]])
```

**Return data type:** numeric

**Arguments:**

- **value:** The sample values to be evaluated. The sample values must be logically grouped as specified by exactly two values in **group**. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **grp:** The field containing the names of each of the two sample groups. If a field name for the group is not provided in the load script, the field will automatically be given the name **Type**.
- **sig:** The two-tailed level of significance can be specified in **sig**. If omitted, **sig** is set to 0.025, resulting in a 95% confidence interval.

- `eq_var`: If `eq_var` is specified as False (0), separate variances of the two samples will be assumed. If `eq_var` is specified as True (1), equal variances between the samples will be assumed.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
TTest_upper(Group, Value)
TTest_upper(Group, Value, sig, false)
```

### TTestw\_conf

**TTestw\_conf()** returns the aggregated t value for two independent series of values.

This function applies to two independent samples student's t-tests where the input data series is given in weighted two-column format.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
TTestw_conf (weight, grp, value [, sig [, eq_var]])
```

**Return data type:** numeric

### Arguments:

- `value`: The sample values to be evaluated. The sample values must be logically grouped as specified by exactly two values in `group`. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- `weight`: Each value in `value` can be counted one or more times according to a corresponding weight value in `weight`.
- `grp`: The field containing the names of each of the two sample groups. If a field name for the group is not provided in the load script, the field will automatically be given the name **Type**.
- `sig`: The two-tailed level of significance can be specified in `sig`. If omitted, `sig` is set to 0.025, resulting in a 95% confidence interval.
- `eq_var`: If `eq_var` is specified as False (0), separate variances of the two samples will be assumed. If `eq_var` is specified as True (1), equal variances between the samples will be assumed.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
TTestw_conf(weight, Group, value)
TTestw_conf(weight, Group, value, sig, false)
```

### TTestw\_df

**TTestw\_df()** returns the aggregated student's t-test df value (degrees of freedom) for two independent series of values.

This function applies to two independent samples student's t-tests where the input data series is given in weighted two-column format.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
TTestw_df (weight, grp, value [, eq_var])
```

**Return data type:** numeric

### Arguments:

- **value:** The sample values to be evaluated. The sample values must be logically grouped as specified by exactly two values in **group**. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **weight:** Each value in **value** can be counted one or more times according to a corresponding weight value in **weight**.
- **grp:** The field containing the names of each of the two sample groups. If a field name for the group is not provided in the load script, the field will automatically be given the name **Type**.
- **eq\_var:** If **eq\_var** is specified as False (0), separate variances of the two samples will be assumed. If **eq\_var** is specified as True (1), equal variances between the samples will be assumed.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
TTestw_df(weight, Group, value)
TTestw_df(weight, Group, value, false)
```

### TTestw\_dif

**TTestw\_dif()** returns the aggregated student's t-test mean difference for two independent series of values.

This function applies to two independent samples student's t-tests where the input data series is given in weighted two-column format.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
TTestw_dif (weight, group, value)
```

**Return data type:** numeric

### Arguments:

- **value:** The sample values to be evaluated. The sample values must be logically grouped as specified by exactly two values in **group**. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **weight:** Each value in **value** can be counted one or more times according to a corresponding weight value in **weight**.
- **grp:** The field containing the names of each of the two sample groups. If a field name for the group is not provided in the load script, the field will automatically be given the name **Type**.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
TTestw_dif(weight, Group, value)
TTestw_dif(weight, Group, value, false)
```

### **TTestw\_lower**

**TTestw\_lower()** returns the aggregated value for the lower end of the confidence interval for two independent series of values.

This function applies to two independent samples student's t-tests where the input data series is given in weighted two-column format.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
TTestw_lower (weight, grp, value [, sig [, eq_var]])
```

**Return data type:** numeric

**Arguments:**

- **value:** The sample values to be evaluated. The sample values must be logically grouped as specified by exactly two values in **group**. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **weight:** Each value in **value** can be counted one or more times according to a corresponding weight value in **weight**.
- **grp:** The field containing the names of each of the two sample groups. If a field name for the group is not provided in the load script, the field will automatically be given the name **Type**.
- **sig:** The two-tailed level of significance can be specified in **sig**. If omitted, **sig** is set to 0.025, resulting in a 95% confidence interval.
- **eq\_var:** If **eq\_var** is specified as False (0), separate variances of the two samples will be assumed. If **eq\_var** is specified as True (1), equal variances between the samples will be assumed.

**Limitations:**

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

**Examples:**

```
TTestw_lower(weight, Group, value)
TTestw_lower(weight, Group, value, sig, false)
```

**TTestw\_sig**

**TTestw\_sig()** returns the aggregated student's t-test 2-tailed level of significance for two independent series of values.

This function applies to two independent samples student's t-tests where the input data series is given in weighted two-column format.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

**Syntax:**

```
TTestw_sig (weight, grp, value [, eq_var])
```

**Return data type:** numeric

**Arguments:**

- **value:** The sample values to be evaluated. The sample values must be logically grouped as specified by exactly two values in **group**. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.

- **weight**: Each value in **value** can be counted one or more times according to a corresponding **weight** value in **weight**.
- **grp**: The field containing the names of each of the two sample groups. If a field name for the group is not provided in the load script, the field will automatically be given the name **Type**.
- **eq\_var**: If **eq\_var** is specified as False (0), separate variances of the two samples will be assumed. If **eq\_var** is specified as True (1), equal variances between the samples will be assumed.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
TTestw_sig(weight, Group, value)
TTestw_sig(weight, Group, value, false)
```

### TTestw\_sterr

**TTestw\_sterr()** returns the aggregated student's t-test standard error of the mean difference for two independent series of values.

This function applies to two independent samples student's t-tests where the input data series is given in weighted two-column format.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
TTestw_sterr (weight, grp, value [, eq_var])
```

**Return data type:** numeric

### Arguments:

- **value**: The sample values to be evaluated. The sample values must be logically grouped as specified by exactly two values in **group**. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **weight**: Each value in **value** can be counted one or more times according to a corresponding **weight** value in **weight**.
- **grp**: The field containing the names of each of the two sample groups. If a field name for the group is not provided in the load script, the field will automatically be given the name **Type**.
- **eq\_var**: If **eq\_var** is specified as False (0), separate variances of the two samples will be assumed. If **eq\_var** is specified as True (1), equal variances between the samples will be assumed.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
TTestw_sterr(weight, Group, value)
TTestw_sterr(weight, Group, value, false)
```

### TTestw\_t

**TTestw\_t()** returns the aggregated t value for two independent series of values.

This function applies to two independent samples student's t-tests where the input data series is given in weighted two-column format.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
ttestw_t (weight, grp, value [, eq_var])
```

**Return data type:** numeric

### Arguments:

- **value:** The sample values to be evaluated. The sample values must be logically grouped as specified by exactly two values in **group**. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **weight:** Each value in **value** can be counted one or more times according to a corresponding weight value in **weight**.
- **grp:** The field containing the names of each of the two sample groups. If a field name for the group is not provided in the load script, the field will automatically be given the name **Type**.
- **eq\_var:** If **eq\_var** is specified as False (0), separate variances of the two samples will be assumed. If **eq\_var** is specified as True (1), equal variances between the samples will be assumed.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
TTestw_t(weight, Group, value)
TTestw_t(weight, Group, value, false)
```

### TTestw\_upper

**TTestw\_upper()** returns the aggregated value for the upper end of the confidence interval for two independent series of values.

This function applies to two independent samples student's t-tests where the input data series is given in weighted two-column format.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

#### Syntax:

```
TTestw_upper (weight, grp, value [, sig [, eq_var]])
```

**Return data type:** numeric

#### Arguments:

- **value:** The sample values to be evaluated. The sample values must be logically grouped as specified by exactly two values in **group**. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **weight:** Each value in **value** can be counted one or more times according to a corresponding weight value in **weight**.
- **grp:** The field containing the names of each of the two sample groups. If a field name for the group is not provided in the load script, the field will automatically be given the name **Type**.
- **sig:** The two-tailed level of significance can be specified in **sig**. If omitted, **sig** is set to 0.025, resulting in a 95% confidence interval.
- **eq\_var:** If **eq\_var** is specified as False (0), separate variances of the two samples will be assumed. If **eq\_var** is specified as True (1), equal variances between the samples will be assumed.

#### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

#### Examples:

```
TTestw_upper(weight, Group, value)
TTestw_upper(weight, Group, value, sig, false)
```

### TTest1\_conf

**TTest1\_conf()** returns the aggregated confidence interval value for a series of values.

This function applies to one-sample student's t-tests.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
TTest1_conf (value [, sig])
```

**Return data type:** numeric

### Arguments:

- **value:** The samples to be evaluated. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **sig:** The two-tailed level of significance can be specified in **sig**. If omitted, **sig** is set to 0.025, resulting in a 95% confidence interval.

| Argument | Description                                                                                                                                                 |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value    | The samples to be evaluated. If a field name for the sample values is not provided in the load script, the field will automatically be named <b>Value</b> . |
| sig      | The two-tailed level of significance can be specified in <b>sig</b> . If omitted, <b>sig</b> is set to 0.025, resulting in a 95% confidence interval.       |

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
TTest1_conf(value)
TTest1_conf(value, 0.005)
```

### TTest1\_df

**TTest1\_df()** returns the aggregated student's t-test df value (degrees of freedom) for a series of values.

This function applies to one-sample student's t-tests.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
TTest1_df (value)
```

**Return data type:** numeric

### Arguments:

- **value:** The samples to be evaluated. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Example:

```
TTest1_df(value)
```

### TTest1\_dif

**TTest1\_dif()** returns the aggregated student's t-test mean difference for a series of values.

This function applies to one-sample student's t-tests.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
TTest1_dif (value)
```

**Return data type:** numeric

### Arguments:

- **value:** The samples to be evaluated. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Example:

```
TTest1_dif(value)
```

### TTest1\_lower

**TTest1\_lower()** returns the aggregated value for the lower end of the confidence interval for a series of values.

This function applies to one-sample student's t-tests.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
TTest1_lower (value [, sig])
```

**Return data type:** numeric

**Arguments:**

- **value:** The samples to be evaluated. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **sig:** The two-tailed level of significance can be specified in **sig**. If omitted, **sig** is set to 0.025, resulting in a 95% confidence interval.

**Limitations:**

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

**Examples:**

```
TTest1_lower(value)
TTest1_lower(value, 0.005)
```

**TTest1\_sig**

**TTest1\_sig()** returns the aggregated student's t-test 2-tailed level of significance for a series of values.

This function applies to one-sample student's t-tests.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

**Syntax:**

```
TTest1_sig (value)
```

**Return data type:** numeric

**Arguments:**

- **value:** The samples to be evaluated. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.

**Limitations:**

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

**Example:**

```
TTest1_sig(value)
```

### TTest1\_sterr

**TTest1\_sterr()** returns the aggregated student's t-test standard error of the mean difference for a series of values.

This function applies to one-sample student's t-tests.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

#### Syntax:

```
TTest1_sterr (value)
```

**Return data type:** numeric

#### Arguments:

- **value:** The samples to be evaluated. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.

#### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

#### Example:

```
TTest1_sterr(value)
```

### TTest1\_t

**TTest1\_t()** returns the aggregated t value for a series of values.

This function applies to one-sample student's t-tests.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

#### Syntax:

```
TTest1_t (value)
```

**Return data type:** numeric

#### Arguments:

- **value:** The samples to be evaluated. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Example:

```
TTest1_t(value)
```

### TTest1\_upper

**TTest1\_upper()** returns the aggregated value for the upper end of the confidence interval for a series of values.

This function applies to one-sample student's t-tests.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
TTest1_upper (value [, sig])
```

**Return data type:** numeric

### Arguments:

- **value:** The samples to be evaluated. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **sig:** The two-tailed level of significance can be specified in **sig**. If omitted, **sig** is set to 0.025, resulting in a 95% confidence interval.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
TTest1_upper(value)
```

```
TTest1_upper(value, 0.005)
```

### TTest1w\_conf

**TTest1w\_conf()** is a **numeric** function that returns the aggregated confidence interval value for a series of values.

This function applies to one-sample student's t-tests where the input data series is given in weighted two-column format.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
TTest1w_conf (weight, value [, sig])
```

**Return data type:** numeric

### Arguments:

- **value:** The samples to be evaluated. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **weight:** Each value in **value** can be counted one or more times according to a corresponding weight value in **weight**.
- **sig:** The two-tailed level of significance can be specified in **sig**. If omitted, **sig** is set to 0.025, resulting in a 95% confidence interval.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
TTest1w_conf(weight, value)
TTest1w_conf(weight, value, 0.005)
```

### **TTest1w\_df**

**TTest1w\_df()** returns the aggregated student's t-test df value (degrees of freedom) for a series of values.

This function applies to one-sample student's t-tests where the input data series is given in weighted two-column format.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
TTest1w_df (weight, value)
```

**Return data type:** numeric

### Arguments:

- **value:** The samples to be evaluated. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.

- **weight**: Each value in **value** can be counted one or more times according to a corresponding weight value in **weight**.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Example:

```
TTest1w_df(weight, value)
```

### TTest1w\_dif

**TTest1w\_dif()** returns the aggregated student's t-test mean difference for a series of values.

This function applies to one-sample student's t-tests where the input data series is given in weighted two-column format.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
TTest1w_dif (weight, value)
```

**Return data type:** numeric

### Arguments:

- **value**: The samples to be evaluated. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **weight**: Each value in **value** can be counted one or more times according to a corresponding weight value in **weight**.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Example:

```
TTest1w_dif(weight, value)
```

### TTest1w\_lower

**TTest1w\_lower()** returns the aggregated value for the lower end of the confidence interval for a series of values.

This function applies to one-sample student's t-tests where the input data series is given in weighted two-column format.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
TTest1w_lower (weight, value [, sig])
```

**Return data type:** numeric

### Arguments:

- **value:** The samples to be evaluated. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **weight:** Each value in **value** can be counted one or more times according to a corresponding weight value in **weight**.
- **sig:** The two-tailed level of significance can be specified in **sig**. If omitted, **sig** is set to 0.025, resulting in a 95% confidence interval.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
TTest1w_lower(weight, value)
TTest1w_lower(weight, value, 0.005)
```

### **TTest1w\_sig**

**TTest1w\_sig()** returns the aggregated student's t-test 2-tailed level of significance for a series of values.

This function applies to one-sample student's t-tests where the input data series is given in weighted two-column format.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
TTest1w_sig (weight, value)
```

**Return data type:** numeric

### Arguments:

- **value:** The samples to be evaluated. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.

- **weight**: Each value in **value** can be counted one or more times according to a corresponding weight value in **weight**.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Example:

```
TTest1w_sig(weight, value)
```

### TTest1w\_sterr

**TTest1w\_sterr()** returns the aggregated student's t-test standard error of the mean difference for a series of values.

This function applies to one-sample student's t-tests where the input data series is given in weighted two-column format.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
TTest1w_sterr (weight, value)
```

**Return data type:** numeric

### Arguments:

- **value**: The samples to be evaluated. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **weight**: Each value in **value** can be counted one or more times according to a corresponding weight value in **weight**.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Example:

```
TTest1w_sterr(weight, value)
```

### TTest1w\_t

**TTest1w\_t()** returns the aggregated t value for a series of values.

This function applies to one-sample student's t-tests where the input data series is given in weighted two-column format.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
TTest1w_t (weight, value)
```

**Return data type:** numeric

### Arguments:

- **value:** The samples to be evaluated. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **weight:** Each value in **value** can be counted one or more times according to a corresponding weight value in **weight**.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Example:

```
TTest1w_t(weight, value)
```

### **TTest1w\_upper**

**TTest1w\_upper()** returns the aggregated value for the upper end of the confidence interval for a series of values.

This function applies to one-sample student's t-tests where the input data series is given in weighted two-column format.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
TTest1w_upper (weight, value [, sig])
```

**Return data type:** numeric

### Arguments:

- **value:** The samples to be evaluated. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **weight:** Each value in **value** can be counted one or more times according to a corresponding weight value in **weight**.

- `sig`: The two-tailed level of significance can be specified in `sig`. If omitted, `sig` is set to 0.025, resulting in a 95% confidence interval.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
TTest1w_upper(weight, value)
TTest1w_upper(weight, value, 0.005)
```

### Z-test functions

A statistical examination of two population means. A two sample z-test examines whether two samples are different and is commonly used when two normal distributions have known variances and when an experiment uses a large sample size.

The z-test statistical test functions are grouped according the type of input data series that applies to the function.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

*Loading the sample data (page 1203)*

### One column format functions

The following functions apply to z-tests with simple input data series:

`ztest_conf`

**ZTest\_conf()** returns the aggregated z value for a series of values.

```
ZTest_conf (value [, sigma [, sig]]
```

`ztest_dif`

**ZTest\_dif()** returns the aggregated z-test mean difference for a series of values.

```
ZTest_dif (value [, sigma])
```

`ztest_sig`

**ZTest\_sig()** returns the aggregated z-test 2-tailed level of significance for a series of values.

```
ZTest_sig (value [, sigma])
```

`ztest_sterr`

**ZTest\_sterr()** returns the aggregated z-test standard error of the mean difference for a series of values.

```
ZTest_sterr (value [, sigma])
```

ztest\_z

**ZTest\_z()** returns the aggregated z value for a series of values.

```
ZTest_z (value [, sigma])
```

ztest\_lower

**ZTest\_lower()** returns the aggregated value for the lower end of the confidence interval for two independent series of values.

```
ZTest_lower (grp, value [, sig [, eq_var]])
```

ztest\_upper

**ZTest\_upper()** returns the aggregated value for the upper end of the confidence interval for two independent series of values.

```
ZTest_upper (grp, value [, sig [, eq_var]])
```

### Weighted two-column format functions

The following functions apply to z-tests where the input data series is given in weighted two-column format.

ztestw\_conf

**ZTestw\_conf()** returns the aggregated z confidence interval value for a series of values.

```
ZTestw_conf (weight, value [, sigma [, sig]])
```

ztestw\_dif

**ZTestw\_dif()** returns the aggregated z-test mean difference for a series of values.

```
ZTestw_dif (weight, value [, sigma])
```

ztestw\_lower

**ZTestw\_lower()** returns the aggregated value for the lower end of the confidence interval for two independent series of values.

```
ZTestw_lower (weight, value [, sigma])
```

ztestw\_sig

**ZTestw\_sig()** returns the aggregated z-test 2-tailed level of significance for a series of values.

```
ZTestw_sig (weight, value [, sigma])
```

ztestw\_sterr

**ZTestw\_sterr()** returns the aggregated z-test standard error of the mean difference for a series of values.

```
ZTestw_sterr (weight, value [, sigma])
```

ztestw\_upper

**ZTestw\_upper()** returns the aggregated value for the upper end of the confidence interval for two independent series of values.

```
ZTestw_upper (weight, value [, sigma])
```

ztestw\_z

**ZTestw\_z()** returns the aggregated z value for a series of values.

```
ZTestw_z (weight, value [, sigma])
```

**ZTest\_z**

**ZTest\_z()** returns the aggregated z value for a series of values.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

**Syntax:**

```
ZTest_z (value[, sigma])
```

**Return data type:** numeric

**Arguments:**

- **value:** The sample values to be evaluated. A population mean of 0 is assumed. If you want the test to be performed around another mean, subtract that mean from the sample values.
- **sigma:** If known, the standard deviation can be stated in **sigma**. If **sigma** is omitted the actual sample standard deviation will be used.

**Limitations:**

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

**Example:**

```
zTest_z(Value-TestValue)
```

**ZTest\_sig**

**ZTest\_sig()** returns the aggregated z-test 2-tailed level of significance for a series of values.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

**Syntax:**

```
ZTest_sig (value[, sigma])
```

**Return data type:** numeric

**Arguments:**

- **value:** The sample values to be evaluated. A population mean of 0 is assumed. If you want the test to be performed around another mean, subtract that mean from the sample values.
- **sigma:** If known, the standard deviation can be stated in **sigma**. If **sigma** is omitted the actual sample standard deviation will be used.

**Limitations:**

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

**Example:**

```
ZTest_sig(Value-TestValue)
```

**ZTest\_dif**

**ZTest\_dif()** returns the aggregated z-test mean difference for a series of values.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

**Syntax:**

```
ZTest_dif(value[, sigma])
```

**Return data type:** numeric

**Arguments:**

- **value:** The sample values to be evaluated. A population mean of 0 is assumed. If you want the test to be performed around another mean, subtract that mean from the sample values.
- **sigma:** If known, the standard deviation can be stated in **sigma**. If **sigma** is omitted the actual sample standard deviation will be used.

**Limitations:**

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

**Example:**

```
ZTest_dif(Value-TestValue)
```

**ZTest\_sterr**

**ZTest\_sterr()** returns the aggregated z-test standard error of the mean difference for a series of values.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
ZTest_sterr(value[, sigma])
```

**Return data type:** numeric

### Arguments:

- **value:** The sample values to be evaluated. A population mean of 0 is assumed. If you want the test to be performed around another mean, subtract that mean from the sample values.
- **sigma:** If known, the standard deviation can be stated in **sigma**. If **sigma** is omitted the actual sample standard deviation will be used.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Example:

```
ZTest_sterr(Value-TestValue)
```

### ZTest\_conf

**ZTest\_conf()** returns the aggregated z value for a series of values.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
ZTest_conf(value[, sigma[, sig]])
```

**Return data type:** numeric

### Arguments:

- **value:** The sample values to be evaluated. A population mean of 0 is assumed. If you want the test to be performed around another mean, subtract that mean from the sample values.
- **sigma:** If known, the standard deviation can be stated in **sigma**. If **sigma** is omitted the actual sample standard deviation will be used.
- **sig:** The two-tailed level of significance can be specified in **sig**. If omitted, **sig** is set to 0.025, resulting in a 95% confidence interval.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Example:

```
ZTest_conf(Value-TestValue)
```

### ZTest\_lower

**ZTest\_lower()** returns the aggregated value for the lower end of the confidence interval for two independent series of values.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
ZTest_lower (grp, value [, sig [, eq_var]])
```

**Return data type:** numeric

### Arguments:

- **value:** The sample values to be evaluated. The sample values must be logically grouped as specified by exactly two values in **group**. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **grp:** The field containing the names of each of the two sample groups. If a field name for the group is not provided in the load script, the field will automatically be given the name **Type**.
- **sig:** The two-tailed level of significance can be specified in **sig**. If omitted, **sig** is set to 0.025, resulting in a 95% confidence interval.
- **eq\_var:** If **eq\_var** is specified as False (0), separate variances of the two samples will be assumed. If **eq\_var** is specified as True (1), equal variances between the samples will be assumed.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
ZTest_lower(Group, Value)
ZTest_lower(Group, Value, sig, false)
```

### ZTest\_upper

**ZTest\_upper()** returns the aggregated value for the upper end of the confidence interval for two independent series of values.

This function applies to independent samples student's t-tests.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
ZTest_upper (grp, value [, sig [, eq_var]])
```

**Return data type:** numeric

### Arguments:

- **value:** The sample values to be evaluated. The sample values must be logically grouped as specified by exactly two values in **group**. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **grp:** The field containing the names of each of the two sample groups. If a field name for the group is not provided in the load script, the field will automatically be given the name **Type**.
- **sig:** The two-tailed level of significance can be specified in **sig**. If omitted, **sig** is set to 0.025, resulting in a 95% confidence interval.
- **eq\_var:** If **eq\_var** is specified as False (0), separate variances of the two samples will be assumed. If **eq\_var** is specified as True (1), equal variances between the samples will be assumed.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
ZTest_upper(Group, value)
ZTest_upper(Group, value, sig, false)
```

### ZTestw\_z

**ZTestw\_z()** returns the aggregated z value for a series of values.

This function applies to z-tests where the input data series is given in weighted two-column format.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
ZTestw_z (weight, value [, sigma])
```

**Return data type:** numeric

**Arguments:**

- **value:** The values should be returned by **value**. A sample mean of 0 is assumed. If you want the test to be performed around another mean, subtract that value from the sample values.
- **weight:** Each sample value in **value** can be counted one or more times according to a corresponding weight value in **weight**.
- **sigma:** If known, the standard deviation can be stated in **sigma**. If **sigma** is omitted the actual sample standard deviation will be used.

**Limitations:**

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

**Example:**

```
ZTestw_z(weight, Value-TestValue)
```

**ZTestw\_sig**

**ZTestw\_sig()** returns the aggregated z-test 2-tailed level of significance for a series of values.

This function applies to z-tests where the input data series is given in weighted two-column format.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

**Syntax:**

```
ZTestw_sig (weight, value [, sigma])
```

**Return data type:** numeric

**Arguments:**

- **value:** The values should be returned by **value**. A sample mean of 0 is assumed. If you want the test to be performed around another mean, subtract that value from the sample values.
- **weight:** Each sample value in **value** can be counted one or more times according to a corresponding weight value in **weight**.
- **sigma:** If known, the standard deviation can be stated in **sigma**. If **sigma** is omitted the actual sample standard deviation will be used.

**Limitations:**

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Example:

```
ZTestw_sig(weight, Value-TestValue)
```

### ZTestw\_dif

**ZTestw\_dif()** returns the aggregated z-test mean difference for a series of values.

This function applies to z-tests where the input data series is given in weighted two-column format.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
ZTestw_dif (weight, value [, sigma])
```

**Return data type:** numeric

### Arguments:

- **value:** The values should be returned by **value**. A sample mean of 0 is assumed. If you want the test to be performed around another mean, subtract that value from the sample values.
- **weight:** Each sample value in **value** can be counted one or more times according to a corresponding weight value in **weight**.
- **sigma:** If known, the standard deviation can be stated in **sigma**. If **sigma** is omitted the actual sample standard deviation will be used.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Example:

```
ZTestw_dif(weight, Value-TestValue)
```

### ZTestw\_sterr

**ZTestw\_sterr()** returns the aggregated z-test standard error of the mean difference for a series of values.

This function applies to z-tests where the input data series is given in weighted two-column format.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
ZTestw_sterr (weight, value [, sigma])
```

**Return data type:** numeric

**Arguments:**

- **value:** The values should be returned by **value**. A sample mean of 0 is assumed. If you want the test to be performed around another mean, subtract that value from the sample values.
- **weight:** Each sample value in **value** can be counted one or more times according to a corresponding weight value in **weight**.
- **sigma:** If known, the standard deviation can be stated in **sigma**. If **sigma** is omitted the actual sample standard deviation will be used.

**Limitations:**

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

**Example:**

```
ZTestw_sterr(weight, value-TestValue)
```

**ZTestw\_conf**

**ZTestw\_conf()** returns the aggregated z confidence interval value for a series of values.

This function applies to z-tests where the input data series is given in weighted two-column format.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

**Syntax:**

```
ZTest_conf(weight, value[, sigma[, sig]])
```

**Return data type:** numeric

**Arguments:**

- **value:** The sample values to be evaluated. A population mean of 0 is assumed. If you want the test to be performed around another mean, subtract that mean from the sample values.
- **weight:** Each sample value in **value** can be counted one or more times according to a corresponding weight value in **weight**.
- **sigma:** If known, the standard deviation can be stated in **sigma**. If **sigma** is omitted the actual sample standard deviation will be used.
- **sig:** The two-tailed level of significance can be specified in **sig**. If omitted, **sig** is set to 0.025, resulting in a 95% confidence interval.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Example:

```
ZTestw_conf(weight, value-TestValue)
```

### ZTestw\_lower

**ZTestw\_lower()** returns the aggregated value for the lower end of the confidence interval for two independent series of values.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
ZTestw_lower (grp, value [, sig [, eq_var]])
```

**Return data type:** numeric

### Arguments:

- **value:** The sample values to be evaluated. The sample values must be logically grouped as specified by exactly two values in **group**. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **grp:** The field containing the names of each of the two sample groups. If a field name for the group is not provided in the load script, the field will automatically be given the name **Type**.
- **sig:** The two-tailed level of significance can be specified in **sig**. If omitted, **sig** is set to 0.025, resulting in a 95% confidence interval.
- **eq\_var:** If **eq\_var** is specified as False (0), separate variances of the two samples will be assumed. If **eq\_var** is specified as True (1), equal variances between the samples will be assumed.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
ZTestw_lower(Group, value)
ZTestw_lower(Group, value, sig, false)
```

### ZTestw\_upper

**ZTestw\_upper()** returns the aggregated value for the upper end of the confidence interval for two independent series of values.

This function applies to independent samples student's t-tests.

If the function is used in the load script, the values are iterated over a number of records as defined by a group by clause.

If the function is used in a chart expression, the values are iterated over the chart dimensions.

### Syntax:

```
ZTestw_upper (grp, value [, sig [, eq_var]])
```

**Return data type:** numeric

### Arguments:

- **value:** The sample values to be evaluated. The sample values must be logically grouped as specified by exactly two values in **group**. If a field name for the sample values is not provided in the load script, the field will automatically be named **Value**.
- **grp:** The field containing the names of each of the two sample groups. If a field name for the group is not provided in the load script, the field will automatically be given the name **Type**.
- **sig:** The two-tailed level of significance can be specified in **sig**. If omitted, **sig** is set to 0.025, resulting in a 95% confidence interval.
- **eq\_var:** If **eq\_var** is specified as False (0), separate variances of the two samples will be assumed. If **eq\_var** is specified as True (1), equal variances between the samples will be assumed.

### Limitations:

Text values, NULL values and missing values in the expression value will result in the function returning NULL.

### Examples:

```
ZTestw_upper(Group, Value)
ZTestw_upper(Group, Value, sig, false)
```

### Statistical test function examples

This section includes examples of statistical test functions as applied to charts and the load script.

#### Examples of how to use chi2-test functions in charts

The chi2-test functions are used to find values associated with chi squared statistical analysis. This section describes how to build charts using sample data to find the values of the chi-squared distribution test functions available in QlikView. Please refer to the individual chi2-test chart function topics for descriptions of syntax and arguments.

## 9.8 Loading the data for the samples

There are three sets of sample data describing three different statistical samples to be loaded into the script.

Do the following:

1. Create a new document.
2. Select **Edit Script** in the toolbar and enter the following to the script:

```
// Sample_1 data is pre-aggregated... Note: make sure you set your DecimalSep='.' at the
top of the script.
Sample_1:
LOAD * inline [
Grp,Grade,Count
I,A,15
I,B,7
I,C,9
I,D,20
I,E,26
I,F,19
II,A,10
II,B,11
II,C,7
II,D,15
II,E,21
II,F,16
];
// Sample_2 data is pre-aggregated: If raw data is used, it must be aggregated using
count()...
Sample_2:
LOAD * inline [
Sex,Opinion,OpCount
1,2,58
1,1,11
1,0,10
2,2,35
2,1,25
2,0,23] (delimiter is ',');
// Sample_3a data is transformed using the crosstable statement...
Sample_3a:
crosstable(Gender, Actual) LOAD
Description,
[Men (Actual)] as Men,
[Women (Actual)] as Women;
LOAD * inline [
Men (Actual),Women (Actual),Description
58,35,Agree
11,25,Neutral
10,23,Disagree] (delimiter is ',');
// Sample_3b data is transformed using the crosstable statement...
Sample_3b:
crosstable(Gender, Expected) LOAD
Description,
[Men (Expected)] as Men,
[Women (Expected)] as Women;
LOAD * inline [
Men (Expected),Women (Expected),Description
45.35,47.65,Agree
17.56,18.44,Neutral
16.09,16.91,Disagree] (delimiter is ',');
// Sample_3a and Sample_3b will result in a (fairly harmless) synthetic key...
```
3. Save the script and click **Reload** to load the data.

## 9.9 Creating the chi2-test chart function charts

### Example: Sample 1

Do the following:

1. Add a table box to the sheet and add Grp, Grade, and Count as dimensions.  
This table shows the sample data.
2. Add straight table with the following calculated dimension:  
`valueList('p','df','chi2')`  
This uses the synthetic dimensions function to create labels for the dimensions with the names of the three chi2-test functions.
3. Add the following expression:  
`IF(ValueList('p','df','chi2')='p',Chi2Test_p(Grp,Grade,Count),  
IF(ValueList('p','df','chi2')='df',Chi2Test_df(Grp,Grade,Count),  
Chi2Test_chi2(Grp,Grade,Count)))`  
This has the effect of putting the resulting value of each chi2-test function in the table next to its associated synthetic dimension.
4. Set the number format setting of the expression to **Number** and **Precision to 3**.

*In the expression, you could use the following expression instead:*

```
Pick(Match(ValueList('p','df','chi2'),'p','df','chi2'),Chi2Test_p
(Grp,Grade,Count),Chi2Test_df(Grp,Grade,Count),Chi2Test_chi2(Grp,Grade,Count))
```

### Result:

The resulting table for the chi2-test functions for the Sample 1 data will contain the following values:

| Example results |    |      |
|-----------------|----|------|
| p               | df | Chi2 |
| 0.820           | 5  | 2.21 |

### Example: Sample 2

Do the following:

1. Add another table box to the sheet with Sex, Opinion, and OpCount as dimensions.
2. Make a copy of the results straight table from Sample 1 using the **Copy to Clipboard:/Object** and **Paste Sheet Object** commands. Edit the expression and replace the arguments in all three chi2-test functions with the names of the fields used in the Sample 2 data, for example: `chi2Test_p(Sex,Opinion,OpCount)`.

### Result:

The resulting table for the chi2-test functions for the Sample 2 data will contain the following values:

Example results

| p        | df | Chi2 |
|----------|----|------|
| 0.000309 | 2  | 16.2 |

### Example: Sample 3

Do the following:

1. Create one more table box and one more straight table in the same way as in the examples for Sample 1 and Sample 2 data. In the table box, use the following fields as dimensions: Gender, Description, Actual, and Expected.
2. In the results straight table, use the names of the fields used in the Sample 3 data, for example: `Chi2Test_p(Gender,Description,Actual,Expected)`.

### Result:

The resulting table for the chi2-test functions for the Sample 3 data will contain the following values:

Example results

| p        | df | Chi2 |
|----------|----|------|
| 0.000308 | 2  | 16.2 |

### Examples of how to use chi2-test functions in the load script

The chi2-test functions are used to find values associated with chi squared statistical analysis. This section describes how to use the chi-squared distribution test functions available in QlikView in the load script. Please refer to the individual chi2-test script function topics for descriptions of syntax and arguments.

This example uses a table containing the number of students achieving a grade (A-F) for two groups of students (I and II).

chi2-test example

| -  | A  | B  | C | D  | E  | F  |
|----|----|----|---|----|----|----|
| I  | 15 | 7  | 9 | 20 | 26 | 19 |
| II | 10 | 11 | 7 | 15 | 21 | 16 |

## 9.10 Loading the sample data

Do the following:

1. Create a new document.
2. Select **Edit Script** in the toolbar and enter the following to the script:
 

```
// Sample_1 data is pre-aggregated... Note: make sure you set your DecimalSep='.' at the
top of the script.
sample_1:
LOAD * inline [
Grp,Grade,Count
```

```
I,A,15
I,B,7
I,C,9
I,D,20
I,E,26
I,F,19
II,A,10
II,B,11
II,C,7
II,D,15
II,E,21
II,F,16
];
```

3. Save the script and click **Reload** to load the data.

You have now loaded the sample data.

### 9.11 Loading the chi2-test function values

Now we will load the chi2-test values based on the sample data in a new table, grouped by Grp.

Do the following:

1. Select **Edit Script** in the toolbar and add the following to end of the script:  

```
// Sample_1 data is pre-aggregated... Note: make sure you set your DecimalSep='.' at the
top of the script.
Chi2_table:
LOAD Grp,
Chi2Test_chi2(Grp, Grade, Count) as chi2,
Chi2Test_df(Grp, Grade, Count) as df,
Chi2Test_p(Grp, Grade, Count) as p
resident Sample_1 group by Grp;
```
2. Save the script and click **Reload** to load the data.

You have now loaded the chi2-test values in a table named Chi2\_table.

### 9.12 Results

You can view the resulting chi2-test values in the table viewer, they should look like this:

chi2-test results

| Grp | chi2  | df | p     |
|-----|-------|----|-------|
| I   | 16.00 | 5  | 0.007 |
| II  | 9.40  | 5  | 0.094 |

#### Creating a typical t-test report

A typical student t-test report can include tables with **Group Statistics** and **Independent Samples Test** results. In the following sections we will build these tables using QlikViewt-test functions applied to two independent groups of samples, Observation and Comparison. The corresponding tables for these samples would look like this:

### Group Statistics

Group Statistics example table output

| Type        | N  | Mean  | Standard Deviation | Standard Error Mean |
|-------------|----|-------|--------------------|---------------------|
| Comparison  | 20 | 11.95 | 14.61245           | 3.2674431           |
| Observation | 20 | 27.15 | 12.507997          | 2.7968933           |

### Independent Sample Test

Independent Sample Test example table output

| -                          | t     | df                  | Sig. (2-tailed) | Mean Difference | Standard Error Difference | 95% Confidence Interval of the Difference (Lower) | 95% Confidence Interval of the Difference (Upper) |
|----------------------------|-------|---------------------|-----------------|-----------------|---------------------------|---------------------------------------------------|---------------------------------------------------|
| Equal Variance not Assumed | 3.534 | 37.1167173358<br>23 | 0.001           | 15.2            | 4.30101                   | 6.48625                                           | 23.9137                                           |
| Equal Variance Assumed     | 3.534 | 38                  | 0.001           | 15.2            | 4.30101                   | 6.49306                                           | 23.9069                                           |

## 9.13 Loading the sample data

Do the following:

1. Create a new document.
2. Select **Edit Script** in the toolbar and enter the following to the script:

```
Table1:
crosstable LOAD recno() as ID, * inline [
observation|Comparison
35|2
40|27
12|38
15|31
21|1
14|19
46|1
10|34
28|3
48|1
16|2
30|3
32|2
48|1
31|2
```

```

22|1
12|3
39|29
19|37
25|2] (delimiter is '|');

```

In this load script, **recno()** is included because **crosstable** requires three arguments. So, **recno()** simply provides an extra argument, in this case an ID for each row. Without it, **Comparison** sample values would not be loaded.

3. Save the script and click **Reload** to load the data.

### 9.14 Creating the Group Statistics table

Do the following:

1. Add a straight table on the sheet and select Type as a dimension.
2. Add the following expressions:

Expressions to add

| Label               | Expression   |
|---------------------|--------------|
| N                   | Count(Value) |
| Mean                | Avg(Value)   |
| Standard Deviation  | Stdev(Value) |
| Standard Error Mean | Sterr(Value) |

3. Make sure that Type is at the top of the sorting list.

**Result:**

A Group Statistics table for these samples would look like this:

Group Statistics example table output

| Type        | N  | Mean  | Standard Deviation | Standard Error Mean |
|-------------|----|-------|--------------------|---------------------|
| Comparison  | 20 | 11.95 | 14.61245           | 3.2674431           |
| Observation | 20 | 27.15 | 12.507997          | 2.7968933           |

### 9.15 Creating the Two Independent Sample Student's T-test table

Do the following:

1. Add a table on the sheet.
2. Add the following calculated dimension as a dimension to the table. `=valueList (Dual('Equal Variance not Assumed', 0), Dual('Equal Variance Assumed', 1))`
3. Add the following expressions:

## 9 Script syntax and chart functions

### Expressions to add

| Label                                             | Expression                                                                                                                                                                   |
|---------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| conf                                              | if(ValueList (Dual('Equal Variance not Assumed', 0), Dual('Equal Variance Assumed', 1)),TTest_conf(Type, Value),TTest_conf(Type, Value, 0))                                  |
| t                                                 | if(ValueList (Dual('Equal Variance not Assumed', 0), Dual('Equal Variance Assumed', 1)),TTest_t(Type, Value),TTest_t(Type, Value, 0))                                        |
| df                                                | if(ValueList (Dual('Equal Variance not Assumed', 0), Dual('Equal Variance Assumed', 1)),TTest_df(Type, Value),TTest_df(Type, Value, 0))                                      |
| Sig. (2-tailed)                                   | if(ValueList (Dual('Equal Variance not Assumed', 0), Dual('Equal Variance Assumed', 1)),TTest_sig(Type, Value),TTest_sig(Type, Value, 0))                                    |
| Mean Difference                                   | TTest_dif(Type, Value)                                                                                                                                                       |
| Standard Error Difference                         | if(ValueList (Dual('Equal Variance not Assumed', 0), Dual('Equal Variance Assumed', 1)),TTest_sterr(Type, Value),TTest_sterr(Type, Value, 0))                                |
| 95% Confidence Interval of the Difference (Lower) | if(ValueList (Dual('Equal Variance not Assumed', 0), Dual('Equal Variance Assumed', 1)),TTest_lower(Type, Value,(1-(95)/100)/2),TTest_lower (Type, Value,(1-(95)/100)/2, 0)) |
| 95% Confidence Interval of the Difference (Upper) | if(ValueList (Dual('Equal Variance not Assumed', 0), Dual('Equal Variance Assumed', 1)),TTest_upper(Type, Value,(1-(95)/100)/2),TTest_upper (Type, Value,(1-(95)/100)/2, 0)) |

### Result:

An **Independent Sample Test** table for these samples would look like this:

Independent Sample Test example table output

| -                          | t     | df              | Sig. (2-tailed) | Mean Difference | Standard Error Difference | 95% Confidence Interval of the Difference (Lower) | 95% Confidence Interval of the Difference (Upper) |
|----------------------------|-------|-----------------|-----------------|-----------------|---------------------------|---------------------------------------------------|---------------------------------------------------|
| Equal Variance not Assumed | 3.534 | 37.116717335823 | 0.001           | 15.2            | 4.30101                   | 6.48625                                           | 23.9137                                           |
| Equal Variance Assumed     | 3.534 | 38              | 0.001           | 15.2            | 4.30101                   | 6.49306                                           | 23.9069                                           |

### Examples of how to use z-test functions

The z-test functions are used to find values associated with z-test statistical analysis for large data samples, usually greater than 30, and where the variance is known. This section describes how to build charts using sample data to find the values of the z-test functions available in QlikView. Please refer to the individual z-test chart function topics for descriptions of syntax and arguments.

## 9.16 Loading the sample data

The sample data used here is the same as that used in the t-test function examples. The sample data size would normally be considered too small for z-test analysis, but is sufficient for the purposes of illustrating the use of the different z-test functions in QlikView.

Do the following:

1. Create a new document.

*If you created a document for the t-test functions, you could use that and create a new sheet for these functions.*

2. Select **Edit Script** in the toolbar and enter the following to the script:

```
Table1:
crosstable LOAD recno() as ID, * inline [
observation|Comparison
35|2
40|27
12|38
15|31
21|1
14|19
46|1
10|34
28|3
48|1
16|2
30|3
32|2
48|1
31|2
22|1
12|3
39|29
19|37
25|2] (delimiter is '|');
```

In this load script, **recno()** is included because **crosstable** requires three arguments. So, **recno()** simply provides an extra argument, in this case an ID for each row. Without it, **Comparison** sample values would not be loaded.

3. Save the script and click **Reload** to load the data.

## 9.17 Creating z-test chart function charts

Do the following:

1. Add a straight table on the sheet and select Type as a dimension.
2. Add the following expressions:

|             | Expressions to add |
|-------------|--------------------|
| Label       | Expression         |
| ZTest Conf  | ZTest_conf(Value)  |
| ZTest Dif   | ZTest_dif(Value)   |
| ZTest Sig   | ZTest_sig(Value)   |
| ZTest Sterr | ZTest_sterr(Value) |
| ZTest Z     | ZTest_z(Value)     |

You might wish to adjust the number formatting of the measures in order to see meaningful values. The table will be easier to read if you set number formatting on most of the expressions to fixed to 2 decimals. But for ZTest Sig, for example, use the number formatting: **Number**, and then adjust the format pattern to **###**.

### Result:

The resulting table for the z-test functions for the sample data will contain the following values:

z-test example table output

| Type       | ZTest Conf | ZTest Dif | ZTest Sig | ZTest Sterr | ZTest Z |
|------------|------------|-----------|-----------|-------------|---------|
| Comparison | 6.40       | 11.95     | 0.000123  | 3.27        | 3.66    |
| Value      | 5.48       | 27.15     | 0.001     | 2.80        | 9.71    |

### 9.18 Creating z-testw chart function charts

The z-testw functions are for use when the input data series occurs in weighted two-column format. The expressions require a value for the argument weight. The examples here use the value 2 throughout, but you could use an expression, which would define a value for weight for each observation.

#### Examples and results:

Using the same sample data and number formatting as for the z-test functions, the resulting table for the z-testw functions will contain the following values:

z-testw example table output

| Type       | ZTestw Conf | ZTestw Dif | ZTestw Sig | ZTestw Sterr | ZTestw Z |
|------------|-------------|------------|------------|--------------|----------|
| Comparison | 3.53        | 2.95       | 5.27e-005  | 1.80         | 3.88     |
| Value      | 2.97        | 34.25      | 0          | 4.52         | 20.49    |

### String aggregation functions

This section describes string-related aggregation functions.

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

#### String aggregation functions in the load script

##### Concat

**Concat()** is used to combine string values. The script function returns the aggregated string concatenation of all values of the expression iterated over a number of records as defined by a **group by** clause.

```
Concat ([distinct] expression [, delimiter [, sort-weight]])
```

##### FirstValue

**FirstValue()** returns the value that was loaded first from the records defined by the expression, sorted by a **group by** clause.

*This function is only available as a script function.*

```
FirstValue (expression)
```

##### LastValue

**LastValue()** returns the value that was loaded last from the records defined by the expression, sorted by a **group by** clause.

*This function is only available as a script function.*

```
LastValue (expression)
```

##### MaxString

**MaxString()** finds string values in the expression and returns the last text value sorted over a number of records, as defined by a **group by** clause.

```
MaxString (expression)
```

##### MinString

**MinString()** finds string values in the expression and returns the first text value sorted over a number of records, as defined by a **group by** clause.

```
MinString (expression)
```

#### String aggregation functions in charts

The following chart functions are available for aggregating strings in charts.

### Concat

**Concat()** is used to combine string values. The function returns the aggregated string concatenation of all the values of the expression evaluated over each dimension.

```
Concat - chart function({[SetExpression] [DISTINCT] [TOTAL [<fld{, fld}>]]
string[, delimiter[, sort_weight]])
```

### MaxString

**MaxString()** finds string values in the expression or field and returns the last text value in the text sort order.

```
MaxString - chart function({[SetExpression] [TOTAL [<fld{, fld}>]]} expr)
```

### MinString

**MinString()** finds string values in the expression or field and returns the first text value in the text sort order.

```
MinString - chart function({[SetExpression] [TOTAL [<fld {, fld}>]]} expr)
```

### Concat

**Concat()** is used to combine string values. The script function returns the aggregated string concatenation of all values of the expression iterated over a number of records as defined by a **group by** clause.

#### Syntax:

```
Concat ([distinct] string [, delimiter [, sort-weight]])
```

**Return data type:** string

#### Arguments:

The expression or field containing the string to be processed.

Concat arguments

| Argument    | Description                                                                                                                                                                                         |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| string      | The expression or field containing the string to be processed.                                                                                                                                      |
| delimiter   | Each value may be separated by the string found in delimiter.                                                                                                                                       |
| sort-weight | The order of concatenation may be determined by the value of the dimension <b>sort-weight</b> , if present, with the string corresponding to the lowest value appearing first in the concatenation. |
| distinct    | If the word <b>distinct</b> occurs before the expression, all duplicates are disregarded.                                                                                                           |

#### Examples and results:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

### Examples and results

| Example                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Result field                                                                                                                                                        | Result value                                                            |

### Concat - chart function

**Concat()** is used to combine string values. The function returns the aggregated string concatenation of all the values of the expression evaluated over each dimension.

#### Syntax:

```
Concat ([SetExpression] [DISTINCT] [TOTAL [<fld{, fld}>]] string[, delimiter
[, sort_weight]])
```

**Return data type:** string

#### Arguments:

- **string:** The expression or field containing the string to be processed.
- **delimiter:** Each value may be separated by the string found in delimiter.

- **sort-weight**: The order of concatenation may be determined by the value of the dimension **sort-weight**, if present, with the string corresponding to the lowest value appearing first in the concatenation.
- **SetExpression**: By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **DISTINCT**: If the word **DISTINCT** occurs before the function arguments, duplicates resulting from the evaluation of the function arguments are disregarded.
- **TOTAL**: If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

### Examples:

Examples and results

| Example                                        | Result                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Concat(Team)                                   | The table is constructed from the dimensions SalesGroup and Amount, and variations on the measure Concat(Team). Ignoring the Totals result, note that even though there is data for eight values of Team spread across two values of SalesGroup, the only result of the measure Concat(Team) that concatenates more than one Team string value in the table is the row containing the dimension Amount 20000, which gives the result BetaGammaGamma. This is because there are three values for the Amount 20000 in the input data. All other results remain unconcatenated when the measure is spanned across the dimensions because there is only one value of Team for each combination of SalesGroup and Amount. |
| Concat (DISTINCT Team, ', ')                   | Beta, Gamma. because the DISTINCT qualifier means the duplicate Gamma result is disregarded. Also, the delimiter argument is defined as a comma followed by a space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Concat (TOTAL <SalesGroup> Team)               | All the string values for all values of Team are concatenated if the TOTAL qualifier is used. With the field selection <SalesGroup> specified, this divides the results into the two values of the dimension SalesGroup. For the SalesGroupEast, the results are AlphaBetaDeltaGammaGamma. For the SalesGroupWest, the results are EpsilonEtaThetaZeta.                                                                                                                                                                                                                                                                                                                                                              |
| Concat (TOTAL <SalesGroup> Team, '; ', Amount) | By adding the argument for <b>sort-weight</b> : Amount, the results are ordered by the value of the dimension Amount. The results becomes DeltaBetaGammaGammaAlpha and EtaEpsilonZetaTheta.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

### Data used in examples:

```
TeamData:
LOAD * inline [
SalesGroup|Team|Date|Amount
East|Gamma|01/05/2013|20000
```

```

East|Gamma|02/05/2013|20000
West|Zeta|01/06/2013|19000
East|Alpha|01/07/2013|25000
East|Delta|01/08/2013|14000
West|Epsilon|01/09/2013|17000
West|Eta|01/10/2013|14000
East|Beta|01/11/2013|20000
West|Theta|01/12/2013|23000
] (delimiter is '|');

```

Example data in table form

| SalesGroup | Amount | Concat(Team)   | Concat(TOTAL <SalesGroup> Team) |
|------------|--------|----------------|---------------------------------|
| East       | 25000  | Alpha          | AlphaBetaDeltaGammaGamma        |
| East       | 20000  | BetaGammaGamma | AlphaBetaDeltaGammaGamma        |
| East       | 14000  | Delta          | AlphaBetaDeltaGammaGamma        |
| West       | 17000  | Epsilon        | EpsilonEtaThetaZeta             |
| West       | 14000  | Eta            | EpsilonEtaThetaZeta             |
| West       | 23000  | Theta          | EpsilonEtaThetaZeta             |
| West       | 19000  | Zeta           | EpsilonEtaThetaZeta             |

### FirstValue

**FirstValue()** returns the value that was loaded first from the records defined by the expression, sorted by a **group by** clause.

*This function is only available as a script function.*

### Syntax:

```
FirstValue (expr)
```

**Return data type:** dual

### Arguments:

FirstValue arguments

| Argument | Description                                                 |
|----------|-------------------------------------------------------------|
| expr     | The expression or field containing the data to be measured. |

### Limitations:

If no text value is found, NULL is returned.

### Examples and results:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

Examples and results

| Example                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Result field                       | Result value                             |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|------------------------------------------|
| <pre>TeamData: LOAD * inline [ SalesGroup Team Date Amount East Gamma 01/05/2013 20000 East Gamma 02/05/2013 20000 west Zeta 01/06/2013 19000 East Alpha 01/07/2013 25000 East Delta 01/08/2013 14000 west Epsilon 01/09/2013 17000 west Eta 01/10/2013 14000 East Beta 01/11/2013 20000 west Theta 01/12/2013 23000 ] (delimiter is ' ');  FirstValue1: LOAD SalesGroup,FirstValue(Team) as FirstTeamLoaded Resident TeamData Group By SalesGroup;</pre> | SalesGroup<br><br>East<br><br>West | FirstTeamLoaded<br><br>Gamma<br><br>Zeta |

### LastValue

**LastValue()** returns the value that was loaded last from the records defined by the expression, sorted by a **group by** clause.

*This function is only available as a script function.*

### Syntax:

```
LastValue (expr)
```

**Return data type:** dual

### Arguments:

LastValue arguments

| Argument | Description                                                 |
|----------|-------------------------------------------------------------|
| expr     | The expression or field containing the data to be measured. |

### Limitations:

If no text value is found, NULL is returned.

### Examples and results:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in our document to see the result.

Examples and results

| Example                                                                                                                                                                                                                                                                                                                                                                                                                                                | Result field                       | Result value                            |

### MaxString

**MaxString()** finds string values in the expression and returns the last text value sorted over a number of records, as defined by a **group by** clause.

#### Syntax:

```
MaxString (expr)
```

**Return data type:** dual

#### Arguments:

MaxString arguments

| Argument | Description                                                 |
|----------|-------------------------------------------------------------|
| expr     | The expression or field containing the data to be measured. |

#### Limitations:

If no text value is found, NULL is returned.

### Examples and results:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

### Examples and results

| Example                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Result field                       | Result value                                   |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|------------------------------------------------|
| <b>TeamData:</b><br>LOAD * inline [<br>SalesGroup Team Date Amount<br>East Gamma 01/05/2013 20000<br>East Gamma 02/05/2013 20000<br>West Zeta 01/06/2013 19000<br>East Alpha 01/07/2013 25000<br>East Delta 01/08/2013 14000<br>West Epsilon 01/09/2013 17000<br>West Eta 01/10/2013 14000<br>East Beta 01/11/2013 20000<br>West Theta 01/12/2013 23000<br>] (delimiter is ' ');<br><br><b>Concat1:</b><br>LOAD SalesGroup,MaxString(Team) as MaxString1 Resident<br>TeamData Group By SalesGroup; | SalesGroup<br><br>East<br><br>West | MaxString1<br><br>Gamma<br><br>Zeta            |

### MaxString - chart function

**MaxString()** finds string values in the expression or field and returns the last text value in the text sort order.

#### Syntax:

```
MaxString ({ [SetExpression] [TOTAL [<fld{, fld}>]] } expr)
```

**Return data type:** dual

#### Arguments:

- **expr:** The expression or field containing the data to be measured..
- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

#### Limitations:

If the expression contains no values with a string representation NULL is returned.

### Examples:

*This table represents all values of the dimension Customer with corresponding Product values. In an actual table chart on a sheet, there will be a row for each value of Customer and Product.*

#### Examples and results

| Example          | Result                                                                                                                                                                                                                                |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MaxString (Team) | There are three values of 20000 for the dimension Amount: two of Gamma (on different dates), and one of Beta. The result of the measure MaxString (Team) is therefore Gamma, because this is the highest value in the sorted strings. |
| MaxString (Date) | 2013/11/01 is the greatest Date value of the three associated with the dimension Amount. This assumes your script has the SET statement <code>SET DateFormat='YYYY-MM-DD'</code> ;                                                    |

### Data used in examples:

```
TeamData:
LOAD * inline [
SalesGroup|Team|Date|Amount
East|Gamma|01/05/2013|20000
East|Gamma|02/05/2013|20000
West|Zeta|01/06/2013|19000
East|Alpha|01/07/2013|25000
East|Delta|01/08/2013|14000
West|Epsilon|01/09/2013|17000
West|Eta|01/10/2013|14000
East|Beta|01/11/2013|20000
West|Theta|01/12/2013|23000
] (delimiter is '|');
```

#### Example data in table form

| SalesGroup | Amount | MaxString(Team) | MaxString(Date) |
|------------|--------|-----------------|-----------------|
| East       | 14000  | Delta           | 2013/08/01      |
| East       | 20000  | Gamma           | 2013/11/01      |
| East       | 25000  | Alpha           | 2013/07/01      |
| West       | 14000  | Eta             | 2013/10/01      |
| West       | 17000  | Epsilon         | 2013/09/01      |
| West       | 19000  | Zeta            | 2013/06/01      |
| West       | 23000  | Theta           | 2013/12/01      |

### MinString

**MinString()** finds string values in the expression and returns the first text value sorted over a number of records, as defined by a **group by** clause.

### Syntax:

```
MinString (expr)
```

**Return data type:** dual

### Arguments:

MinString arguments

| Argument | Description                                                 |
|----------|-------------------------------------------------------------|
| expr     | The expression or field containing the data to be measured. |

### Limitations:

If no text value is found, NULL is returned.

### Examples and results:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

Examples and results

| Example                                                                                                                                                                                                                                                                                                                                                                                                                                         | Result field               | Result value                           |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------|----------------------------------------|
| <pre>TeamData: LOAD * inline [ SalesGroup Team Date Amount East Gamma 01/05/2013 20000 East Gamma 02/05/2013 20000 west Zeta 01/06/2013 19000 East Alpha 01/07/2013 25000 East Delta 01/08/2013 14000 west Epsilon 01/09/2013 17000 west Eta 01/10/2013 14000 East Beta 01/11/2013 20000 west Theta 01/12/2013 23000 ] (delimiter is ' ');  Concat1: LOAD SalesGroup,MinString(Team) as MinString1 Resident TeamData Group By SalesGroup;</pre> | SalesGroup<br>East<br>West | MinString1<br>Alpha<br>Epsilon         |

### MinString - chart function

**MinString()** finds string values in the expression or field and returns the first text value in the text sort order.

**Syntax:**

```
MinString ([SetExpression] [TOTAL [<fld {, fld}>]]) expr)
```

**Return data type:** dual

**Arguments:**

- **expr:** The expression or field containing the data to be measured..
- **SetExpression:** By default, the aggregation function will aggregate over the set of possible records defined by the selection. An alternative set of records can be defined by a set analysis expression.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

**Examples:**

Examples and results

| Example          | Result                                                                                                                                                                                                                             |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MinString (Team) | There are three values of 20000 for the dimension Amount: two of Gamma (on different dates), and one of Beta. The result of the measure MinString (Team) is therefore Beta, because this is the first value in the sorted strings. |
| MinString (Date) | 2013/11/01 is the earliest Date value of the three associated with the dimension Amount. This assumes your script has the SET statement SET DateFormat='YYYY-MM-DD';                                                               |

**Data used in examples:**

```
TeamData:
LOAD * inline [
SalesGroup|Team|Date|Amount
East|Gamma|01/05/2013|20000
East|Gamma|02/05/2013|20000
west|Zeta|01/06/2013|19000
East|Alpha|01/07/2013|25000
East|Delta|01/08/2013|14000
west|Epsilon|01/09/2013|17000
west|Eta|01/10/2013|14000
East|Beta|01/11/2013|20000
west|Theta|01/12/2013|23000
] (delimiter is '|');
```

Example data in table form

| SalesGroup | Amount | MaxString(Team) | MaxString(Date) |
|------------|--------|-----------------|-----------------|
| East       | 14000  | Delta           | 2013/08/01      |

| SalesGroup | Amount | MaxString(Team) | MaxString(Date) |
|------------|--------|-----------------|-----------------|
| East       | 20000  | Gamma           | 2013/11/01      |
| East       | 25000  | Alpha           | 2013/07/01      |
| West       | 14000  | Eta             | 2013/10/01      |
| West       | 17000  | Epsilon         | 2013/09/01      |
| West       | 19000  | Zeta            | 2013/06/01      |
| West       | 23000  | Theta           | 2013/12/01      |

### Synthetic dimension functions

A synthetic dimension is created in the document from values generated from the synthetic dimension functions and not directly from fields in the data model. When values generated by a synthetic dimension function are used in a chart as a calculated dimension, this creates a synthetic dimension. Synthetic dimensions allow you to create, for example, charts with dimensions with values arising from your data, that is, dynamic dimensions.

*Synthetic dimensions are not affected by selections.*

The following synthetic dimension functions can be used in charts.

#### ValueList

**ValueList()** returns a set of listed values, which, when used in a calculated dimension, will form a synthetic dimension.

**ValueList - chart function** (v1 {[, Expression]})

#### ValueLoop

**ValueLoop()** returns a set of iterated values which, when used in a calculated dimension, will form a synthetic dimension.

**ValueLoop - chart function**(from [, to [, step ]])

#### ValueList - chart function

**ValueList()** returns a set of listed values, which, when used in a calculated dimension, will form a synthetic dimension.

*In charts with a synthetic dimension created with the **ValueList** function it is possible to reference the dimension value corresponding to a specific expression cell by restating the **ValueList** function with the same parameters in the chart expression. The function may of course be used anywhere in the layout, but apart from when used for synthetic dimensions it will only be meaningful inside an aggregation function.*

*Synthetic dimensions are not affected by selections.*

### Syntax:

```
ValueList(v1 {, ...})
```

**Return data type:** dual

### Arguments:

- v1: Static value (usually a string, but can be a number).
- {, ...}: Optional list of static values.

### Examples:

#### Examples and results

| Example                                                                                                                                                                                                                                   | Result                                                                                                                                                                                |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ValueList('Number of Orders', 'Average Order Size', 'Total Amount')                                                                                                                                                                       | When used to create a dimension in a table, for example, this results in the three string values as row labels in the table. These can then be referenced in an expression.           |
| =IF( ValueList('Number of Orders', 'Average Order Size', 'Total Amount') = 'Number of Orders', count(SaleID), IF( ValueList('Number of Orders', 'Average Order Size', 'Total Amount') = 'Average Order Size', avg(Amount), sum(Amount) )) | This expression takes the values from the created dimension and references them in a nested IF statement as input to three aggregation functions, as seen in the below example table. |

#### Example output in table form

| Created dimension  | Year | Added expression |
|--------------------|------|------------------|
| -                  | -    | <b>522.00</b>    |
| Number of Orders   | 2012 | 5.00             |
| Number of Orders   | 2013 | 7.00             |
| Average Order Size | 2012 | 13.20            |
| Average Order Size | 2013 | 15.43            |
| Total Amount       | 2012 | 66.00            |
| Total Amount       | 2013 | 108.00           |

### Data used in examples:

```
salesPeople:
LOAD * INLINE [
SaleID|SalesPerson|Amount|Year
1|1|12|2013
2|1|23|2013
3|1|17|2013
4|2|9|2013
5|2|14|2013
```

```
6|2|29|2013
7|2|4|2013
8|1|15|2012
9|1|16|2012
10|2|11|2012
11|2|17|2012
12|2|7|2012
] (delimiter is '|');
```

### ValueLoop - chart function

ValueLoop() returns a set of iterated values which, when used in a calculated dimension, will form a synthetic dimension.

The values generated will start with the **from** value and end with the **to** value including intermediate values in increments of step.

*In charts with a synthetic dimension created with the **ValueLoop** function it is possible to reference the dimension value corresponding to a specific expression cell by restating the **ValueLoop** function with the same parameters in the chart expression. The function may of course be used anywhere in the layout, but apart from when used for synthetic dimensions it will only be meaningful inside an aggregation function.*

*Synthetic dimensions are not affected by selections.*

### Syntax:

```
ValueLoop (from [, to [, step]])
```

**Return data type:** dual

### Arguments:

- **from:** Start value in the set of values to be generated.
- **to:** End value in the set of values to be generated.
- **step:** Size of increment between values.

### Examples:

Examples and results

| Example                | Result                                                                                                                                                                                                                |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ValueLoop<br>(1, 10)   | This creates a dimension in a table, for example, that can be used for purposes such as numbered labeling. The example here results in values numbered 1 to 10. These values can then be referenced in an expression. |
| ValueLoop<br>(2, 10,2) | This example results in values numbered 2, 4, 6, 8, and 10 because the argument step has a value of 2.                                                                                                                |

### Nested aggregations

You may come across situations where you need to apply an aggregation to the result of another aggregation. This is referred to as nesting aggregations.

As a general rule, it is not allowed to nest aggregations in a QlikView chart expression. Nesting is only allowed if you:

- Use the **TOTAL** qualifier in the inner aggregation function.

*No more than 100 levels of nesting is allowed.*

### Nested aggregations with the TOTAL qualifier

#### Example:

You want to calculate the sum of the field **Sales**, but only include transactions with an **OrderDate** equal to the last year. The last year can be obtained via the aggregation function **Max (TOTAL Year (OrderDate) )**.

The following aggregation would return the desired result:

```
Sum(If(Year(OrderDate)=Max(TOTAL Year(OrderDate)), Sales))
```

The inclusion of the **TOTAL** qualifier is absolutely necessary for this kind of nesting to be accepted by QlikView, but then again also necessary for the desired comparison. This type of nesting need is quite common and is a good practice.

### Nested aggregations with the aggregation function

Nesting with **TOTAL** is not always enough. For more generic nesting, you will have to use the advanced aggregation function in combination with calculated dimensions.

#### Example:

The following data has been read from the script:

| SalesRep       | Customer                         |
|----------------|----------------------------------|
| Donna Brown    | Bechtel Corporation              |
| Karl Anderson  | Berkeley Design                  |
| Donna Brown    | Capitolnet Marketing Group (CMG) |
| Karl Anderson  | Chas T. Main, Inc.               |
| Karl Anderson  | Degoyler and MacNaughton         |
| Lisa Taylor    | ediSys                           |
| John Smith     | Fimetrics System                 |
| Kathy Johnson  | HCS                              |
| Lisa Taylor    | Homestead Custom                 |
| Lisa Taylor    | Illuminati                       |
| John Smith     | Metro-Goldwyn-Mayer, Inc.        |
| Lisa Taylor    | Onetouch Interactive             |
| Peggie Hurt    | Savetz Publishing                |
| William Fisher | TECC                             |
| William Fisher | VA Research                      |
| Lisa Taylor    | XYZ Operations                   |

An obvious question given this data would be: *"How many customers does each sales representative have?"*.

The question is easily answered using a standard QlikView table:

Some new questions may arise, based on the knowledge just gained: *"How many sales representatives have only a single customer? How many have three or more?"*.

If you disregard the fact that in this simple case, it is easy to count the numbers in the expression columns by hand, these are the types of questions that require a second order of aggregation. The data necessary to make the calculation does not exist in the original fields, nor can it be directly calculated from them.

You need to find a way to use the expression column in the chart above as a dimension in a new chart. This can be obtained by using the advanced aggregation function.

To perform the calculation of the first chart as an inner chart calculation in a new chart, you need to use the following statement for the dimension:

```
=Aggr(Count(Customer), SalesRep)
```

Then, you enter the following expression for the new chart:

```
Count(Distinct SalesRep)
```

The **DISTINCT** qualifier is necessary, since QlikView will count the number of lines in the underlying table.

The resulting table answers the question *"How many sales representatives have 1, 2, 3 etc customers?"*.

Two things are to be noted:

1. The second chart does in no way require the presence of the first chart. It is fully self-contained with the first order aggregation defined within its dimension.
2. The possibilities of nesting do not end here. The dimension arguments of the advanced aggregation function may of course contain calculated dimensions, which in turn make use of the advanced

aggregation function. It would however be relatively easy to loose track of what you are doing when passing the third level of aggregation.

### Sum of rows in pivot tables

The QlikView straight table has a choice for its totals between a simple sum of rows and a calculated expression total. The QlikView pivot table lacks this choice. Pivot table totals are always calculated as expression total.

This is normally a good thing, since it is a rather rare occasion that a sum of rows total is relevant when the two differ.

*Exercise extreme care when using sum of rows on any type of aggregation other than pure sums.*

Having issued that warning, the following section will present an example where the sum of rows total is nevertheless the desired result.

### Example:

In this example, there is a school contest where teams of three students get points by their grades in three different classes. The team may select the highest score within the group for each individual class and then add the three top scores together for a total. The following data has been read from the script:

| Class   | Name  | Score |
|---------|-------|-------|
| English | John  | 5     |
| English | Karen | 1     |
| English | Lisa  | 4     |
| History | John  | 3     |
| History | Karen | 3     |
| History | Lisa  | 2     |
| Math    | John  | 3     |
| Math    | Karen | 3     |
| Math    | Lisa  | 4     |

A straight table with Class as dimension and **Max(Score)** as expression produces the following sum of rows:

| Class   | Max(Score) |
|---------|------------|
| English | 5          |
| History | 3          |
| Math    | 4          |
|         | 12         |

If the straight table was converted to a pivot table that is always calculated as an expression total instead of sum of rows, there would an issue:

| Class   | Max(Score) |
|---------|------------|
| English | 5          |
| History | 3          |
| Math    | 4          |
| Total   | 5          |

In this specific case the total of 12 is expected, and 5 is equally wrong for the purpose. In this case, the **Aggr** function can be used in the expression, not the dimension.

The original expression is enclosed in an **Aggr** function, using the surrounding chart's dimension also as dimension in the **Aggr** function. Now this bundle is used as argument to a **Sum** aggregation. The table will now show the expected total:

| Class   | sum(aggr(max(Score),Class)) |
|---------|-----------------------------|
| English | 5                           |
| History | 3                           |
| Math    | 4                           |
| Total   | 12                          |

The beauty of the advanced aggregation function is that in the individual rows it will evaluate to only a single value. This is because the dimension obviously only has one possible value on each ordinary data row. Since the inner dimension and expression are the same as for the surrounding chart, each value will of course be exactly the same as the result without the enclosing **Sum** and advanced aggregation functions.

For the total row, however, the advanced aggregation function will return three values, one for each value of the dimension field. These will in turn be summed by the **Sum** aggregation. While formally still being an expression total, the result equals that of sum of rows.

### Linear regression in table charts

Linear regression trend lines can be shown in QlikView bitmap charts by means of the **Trendlines** option in the **Expressions** page of **Chart Properties**. It is also possible to display the regression equation.

#### Example:

If you want to display the regression data in e.g. a table chart, the regression must be calculated. The **LINEST\_M** and **LINEST\_B** aggregation functions will give you the required slope and y-intercept values of the linear regression. The **LINEST\_M** and **LINEST\_B** aggregation functions always correspond to a continuous x-axis, which means that you have to make this setting on the **Axes** tab of the chart properties.

To calculate correctly, these functions need to have the entire chart aggregation (expression iterated over dimension) as input. This can be achieved by defining an advanced aggregation function containing the same base expression and dimensions as the containing chart. The advanced aggregation function is then used as parameters to the **LINEST** aggregations. The resulting expression could look like follows:

```
linest_m(total aggr(TransVal,TransID),TransID)*TransID + linest_b(total aggr(TransVal,TransID),TransID)
```

The **Only** function is implied around all occurrences of TransVal and TransID. The **LINEST** aggregations should be made with the **TOTAL** qualifier, else would the regression parameters be calculated per data point rather than for the whole set of data. The result can be seen in the combo chart below where the regression is shown as a regular line expression.

Note that the trend line here is not a traditional QlikView trend line, but a regular expression plotted as line. You can see the difference from the fact that the expression plot, as opposed to a traditional trend line, is not extrapolated outside the first and last data points.

*The calculated values for linear regressions correspond to those displayed in a graph using a continuous axis (recommended). The calculated values may differ from those displayed in a graph using a discrete axis (not recommended). A continuous axis represent calculated values; a discrete axis represent displayed values. This means that NULL values are not included in a discrete axis.*

This chart can converted to a straight table:

The following expressions are used, in order of appearance:

```
Round(Sum(TransVal), '0.1')
Round(LINEST_M(TransVal, TransID, TransID), '0,1')
Round(LINEST_B(TransVal, TransID, TransID), '0,1')
```

### Analytic connections

With analytic connections you are able to integrate external analysis with your business discovery. An analytic connection extends the expressions you can use in load scripts and charts by calling an external calculation engine (when you do this, the calculation engine acts as a server-side extension (SSE)). For example, you could create an analytic connection to R, and use statistical expressions when you load the data.

### Creating an analytic connection

For both QlikView Desktop and QlikView Server (QVS), analytic connections are configured by editing the *Settings.ini*

*QlikView Desktop must be closed before editing the Settings.ini file.  
QlikView Server must be stopped before editing the Settings.ini file.  
After adding new connections or changing existing connections, a restart is required for the changes to take effect.*

*Note that the SSE plugin server must be running before you start QlikView otherwise the connection will not be established.*

Do the following:

1. Open the file *Settings.ini*.  
For QlikView Desktop it is located in *C:\Users\username\AppData\Roaming\QlikTech\QlikView*.

For QlikView Server it is located in *C:\ProgramData\QlikTech\QlikViewServer*.

2. Add the following configuration:

```
[Settings 7]
SSEPlugin=<PluginConfig>[;<PluginConfig>...]
```

Where <PluginConfig> is a comma-separated list of configuration elements containing the following:

<EngineName>, <Address>[, <PathToCertFile>, <RequestTimeout>, <ReconnectTimeout>]

Connection properties

| Property           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <EngineName>       | Name of the analytic connection. Must be unique. This is the mapping/alias to the plugin that will be used from within the expressions in the app. <EngineName> is required to use the plugin functions. For example, SSEPython for a Python plugin or R for an R plugin.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <Address>          | Colon-separated list with two elements:<br><Host>: DNS name (or IP-address) of the plugin.<br><Port>: Port on which the plugin listens.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <PathToCertFile>   | File system path to the folder containing client certificates required for secure communication with the plugin. This path just points to the folder where the certificates are located. You have to make sure that they are actually copied to that folder. The names of the three certificate files must be the following: <i>root_cert.pem</i> , <i>sse_client_cert.pem</i> , <i>sse_client_key.pem</i> . Only mutual authentication (server and client authentication) is allowed.<br><br><div style="border: 1px solid gray; padding: 5px; margin-top: 10px;">  <i>It is optional to set the certificate file path, but, if omitted, insecure communication will be invoked.</i> </div> |
| <RequestTimeout>   | Integer (seconds). Optional. Default value is 0 (infinite). Timeout for message duration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <ReconnectTimeout> | Integer (seconds). Optional. Default value is 20 (seconds). Time before the client tries to reconnect to the plugin after the connection to the plugin was lost.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

3. Open the QlikView Batch *Settings.ini* and add the same configuration as in step 2, to be able to reload the document.  
The default location is  
*C:\Windows\system32\config\systemprofile\AppData\Roaming\QlikTech\QlikViewBatch*.
4. After saving the changes in the *Settings.ini* files, restart QlikView. Now you can use the analytic connection by adding it through the Edit Expression dialog or the Load Script dialog.

### Securing analytic connections

Consider the following best practices to strengthen the security of your QlikView environment when using an analytic connection:

- Install and run the server-side extension (SSE) plugin in a separate, isolated environment without administrator rights. To minimize harm from a malicious script, be aware of which user account is starting the plugin and what access rights this user has in the machine and in the domain.
- For enhanced security, the EvaluateScript functionality can be disabled by setting the configuration parameter `allowsript` to false in the SSE plugin configuration file. This will prevent arbitrary scripts from being executed and allow only predefined functions to be run by the SSE plugin.
- Application developers creating QlikView documents are advised to set any variables used in an SSE expression to a restricted format; for example, you can restrict a variable format to only numeric values.

### Restrictions in using Analytic connections

Analytic connection functionality is disabled when creating a new shared server object.

When an existing sheet object containing an analytic connection expression is copied, the chart property editor is automatically disabled. This means that the chart properties for that sheet object are no longer editable.

### Examples

The following examples show how to set up a server-side extension (SSE) plugin. Here, a Python plugin is used and one or multiple servers are defined.

- One SSE plugin server: `SSEPlugin=SSEPython,localhost:50051`
- Two SSE plugin servers: `SSEPlugin=SSEPython,localhost:50051;R,localhost:50053`
- One SSE plugin server is defined without certificate path but with timeouts set:  
`SSEPlugin=SSEPython,localhost:50051,,0,20`

### Color functions

These functions can be used in expressions associated with setting and evaluating the color properties of chart objects, as well as in load scripts.

*QlikView supports the color functions **qliktechblue** and **qliktechgray** for backwards compatibility reasons, but use of them is not recommended.*

#### ARGB

**ARGB()** is used in expressions to set or evaluate the color properties of a chart object, where the color is defined by a red component **r**, a green component **g**, and a blue component **b**, with an alpha factor (opacity) of **alpha**.

```
ARGB (alpha, r, g, b)
```

### HSL

**HSL()** is used in expressions to set or evaluate the color properties of a chart object, where the color is defined by values of **hue**, **saturation**, and **luminosity** between 0 and 1.

```
HSL (hue, saturation, luminosity)
```

### RGB

**RGB()** is used in expressions to set or evaluate the color properties of a chart object, where the color is defined by a red component **r**, a green component **g**, and a blue component **b** with values between 0 and 255.

```
RGB (r, g, b)
```

### Color

**Color()** is used in expressions to return the color representation of color number *n* in the chart palette shown in the chart properties. The color representation is a dual value where the text representation comes in the form of 'RGB(r, g, b)' where *r*, *g* and *b* are numbers between 0 and 255 representing the red, green and blue color value respectively. The number representation is an integer representing the red, green and blue components.

```
Color (n)
```

### Black

Returns the RGB color representation for black (RGB 0,0,0). Optionally a parameter for alpha factor can be given. An *alpha* of 0 corresponds to full transparency. An *alpha* of 255 corresponds to full opacity. If a value for alpha is not entered, it is assumed to be 255.

```
Black ([alpha])
```

### Darkgray

Returns the RGB color representation for dark gray (RGB 128,128,128). Optionally a parameter for alpha factor can be given. An *alpha* of 0 corresponds to full transparency. An *alpha* of 255 corresponds to full opacity. If a value for alpha is not entered, it is assumed to be 255.

```
Darkgray ([alpha])
```

### Lightgray

Returns the RGB color representation for light gray (RGB 192,192,192). Optionally a parameter for alpha factor can be given. An *alpha* of 0 corresponds to full transparency. An *alpha* of 255 corresponds to full opacity. If a value for alpha is not entered, it is assumed to be 255.

```
Lightgray ([alpha])
```

### White

Returns the RGB color representation for white (RGB 255,255,255). Optionally a parameter for alpha factor can be given. An *alpha* of 0 corresponds to full transparency. An *alpha* of 255 corresponds to full opacity. If a value for alpha is not entered, it is assumed to be 255.

```
White ([alpha])
```

### Blue

Returns the RGB color representation for blue (RGB 0,0,128). Optionally a parameter for alpha factor can be given. An *alpha* of 0 corresponds to full transparency. An *alpha* of 255 corresponds to full opacity. If a value for alpha is not entered, it is assumed to be 255.

**Blue ([alpha])**

### Lightblue

Returns the RGB color representation for light blue (RGB 0,0,255). Optionally a parameter for alpha factor can be given. An *alpha* of 0 corresponds to full transparency. An *alpha* of 255 corresponds to full opacity. If a value for alpha is not entered, it is assumed to be 255.

**Lightblue ([alpha])**

### Green

Returns the RGB color representation for green (RGB 0,128,0). Optionally a parameter for alpha factor can be given. An *alpha* of 0 corresponds to full transparency. An *alpha* of 255 corresponds to full opacity. If a value for alpha is not entered, it is assumed to be 255.

**Green ([alpha])**

### Lightgreen

Returns the RGB color representation for light green (RGB 0,255,0). Optionally a parameter for alpha factor can be given. An *alpha* of 0 corresponds to full transparency. An *alpha* of 255 corresponds to full opacity. If a value for alpha is not entered, it is assumed to be 255.

**Lightgreen ()**

### Cyan

Returns the RGB color representation for cyan (RGB 0,128,128). Optionally a parameter for alpha factor can be given. An *alpha* of 0 corresponds to full transparency. An *alpha* of 255 corresponds to full opacity. If a value for alpha is not entered, it is assumed to be 255.

**Cyan ([alpha])**

### Lightcyan

Returns the RGB color representation for light cyan (RGB 0,255,255). Optionally a parameter for alpha factor can be given. An *alpha* of 0 corresponds to full transparency. An *alpha* of 255 corresponds to full opacity. If a value for alpha is not entered, it is assumed to be 255.

**Lightcyan ()**

### Red

Returns the RGB color representation for red (RGB 128,0,0). Optionally a parameter for alpha factor can be given. An *alpha* of 0 corresponds to full transparency. An *alpha* of 255 corresponds to full opacity. If a value for alpha is not entered, it is assumed to be 255.

**Red ([alpha])**

### Lightred

Returns the RGB color representation for light red (RGB 255,0,0). Optionally a parameter for alpha factor can be given. An *alpha* of 0 corresponds to full transparency. An *alpha* of 255 corresponds to full opacity. If a value for alpha is not entered, it is assumed to be 255.

**Lightred ([alpha])**

### Magenta

Returns the RGB color representation for magenta (RGB 128,0,128). Optionally a parameter for alpha factor can be given. An *alpha* of 0 corresponds to full transparency. An *alpha* of 255 corresponds to full opacity. If a value for alpha is not entered, it is assumed to be 255.

**Magenta ([alpha])**

### Lightmagenta

Returns the RGB color representation for light magenta (RGB 255,0,255). Optionally a parameter for alpha factor can be given. An *alpha* of 0 corresponds to full transparency. An *alpha* of 255 corresponds to full opacity. If a value for alpha is not entered, it is assumed to be 255.

**Lightmagenta ([alpha])**

### Brown

Returns the RGB color representation for brown (RGB 128,128,0). Optionally a parameter for alpha factor can be given. An *alpha* of 0 corresponds to full transparency. An *alpha* of 255 corresponds to full opacity. If a value for alpha is not entered, it is assumed to be 255.

**Brown ([alpha])**

### Yellow

Returns the RGB color representation for yellow (RGB 255,255,0). Optionally a parameter for alpha factor can be given. An *alpha* of 0 corresponds to full transparency. An *alpha* of 255 corresponds to full opacity. If a value for alpha is not entered, it is assumed to be 255.

**Yellow ([alpha])**

### qliktechblue

Returns the RGB color representation for QT blue (RGB 96,112,169). Optionally a parameter for alpha factor can be given. An *alpha* of 0 corresponds to full transparency. An *alpha* of 255 corresponds to full opacity. If a value for alpha is not entered, it is assumed to be 255.

**qliktechblue ([alpha])**

### qliktechgray

Returns the RGB color representation for QT gray (RGB 166,166,166). Optionally a parameter for alpha factor can be given. An *alpha* of 0 corresponds to full transparency. An *alpha* of 255 corresponds to full opacity. If a value for alpha is not entered, it is assumed to be 255.

**qliktechgray ([alpha])**

### Colormix1

**Colormix1()** is used in expressions to return an ARGB value from a two color gradient, based on a value between 0 and 1.

```
Colormix1 (Value , ColorZero , ColorOne)
```

Value is a real number between 0 and 1.

- If Value = 0 ColorZero is returned.
- If Value = 1 ColorOne is returned.
- If  $0 < \text{Value} < 1$  the appropriate intermediate shading is returned.

ColorZero is a valid RGB color representation for the color to be associated with the low end of the interval.

ColorOne is a valid RGB color representation for the color to be associated with the high end of the interval.

#### Example:

```
Colormix1(0.5, red(), blue())
```

returns ARGB(255,64,0,64) (purple)

### Colormix2

**Colormix2()** is used in expressions to return an ARGB value from a two color gradient, based on a value between -1 and 1, with the possibility to specify an intermediate color for the center (0) position.

```
Colormix2 (Value , ColorMinusOne , ColorOne[, ColorZero])
```

Value is a real number between -1 and 1.

- If Value = -1 the first color is returned.
- If Value = 1 the second color is returned.
- If  $-1 < \text{Value} < 1$  the appropriate color mix is returned.

ColorMinusOne is a valid RGB color representation for the color to be associated with the low end of the interval.

ColorOne is a valid RGB color representation for the color to be associated with the high end of the interval.

ColorZero is an optional valid RGB color representation for the color to be associated with the center of the interval.

### SysColor

**SysColor()** returns the ARGB value for the Windows system color nr, where nr corresponds to the parameter to the Windows API function **GetSysColor(nr)**.

```
SysColor (nr)
```

### ColorMapHue

**ColorMapHue()** returns an ARGB value of a color from a colormap that varies the hue component of the HSV color model. The colormap starts with red, passes through yellow, green, cyan, blue, magenta, and returns to red. x must be specified as a value between 0 and 1.

### ColorMapHue (x)

ColorMapJet

**ColorMapJet()** returns an ARGB value of a color from a colormap that starts with blue, passes through cyan, yellow and orange, and returns to red. x must be specified as a value between 0 and 1.

### ColorMapJet (x)

## Pre-defined color functions

The following functions can be used in expressions for pre-defined colors. Each function returns an RGB color representation.

Optionally a parameter for alpha factor can be given, in which case an ARGB color representation is returned. An alpha factor of 0 corresponds to full transparency, and an alpha factor of 255 corresponds to full opacity.

Color functions

| Color function        | RGB value     |
|-----------------------|---------------|
| black([alpha])        | (0,0,0)       |
| blue([alpha])         | (0,0,128)     |
| brown([alpha])        | (128,128,0)   |
| cyan([alpha])         | (0,128,128)   |
| darkgray([alpha])     | (128,128,128) |
| green([alpha])        | (0,128,0)     |
| lightblue([alpha])    | (0,0,255)     |
| lightcyan([alpha])    | (0,255,255)   |
| lightgray([alpha])    | (192,192,192) |
| lightgreen([alpha])   | (0,255,0)     |
| lightmagenta([alpha]) | (255,0,255)   |
| lightred([alpha])     | (255,0,0)     |
| magenta([alpha])      | (128,0,128)   |
| red([alpha])          | (128,0,0)     |
| white([alpha])        | (255,255,255) |
| yellow([alpha])       | (255,255,0)   |

### Examples and results:

- `Blue()` returns `RGB(0,0,128)`.
- `Blue(128)` returns `ARGB(128,0,0,128)`.

### ARGB

**ARGB()** is used in expressions to set or evaluate the color properties of a chart object, where the color is defined by a red component **r**, a green component **g**, and a blue component **b**, with an alpha factor (opacity) of **alpha**.

#### Syntax:

```
ARGB (alpha, r, g, b)
```

**Return data type:** dual

#### Arguments:

- **alpha**: Transparency value in the range 0 - 255. 0 corresponds to full transparency and 255 corresponds to full opacity.
- **r, g, b**: Red, green, and blue component values. A color component of 0 corresponds to no contribution and one of 255 to full contribution.

*All arguments must be expressions that resolve to integers in the range 0 to 255.*

If interpreting the numeric component and formatting it in hexadecimal notation, the values of the color components are easier to see. For example, light green has the number 4 278 255 360, which in hexadecimal notation is FF00FF00. The first two positions 'FF' (255) denote the **alpha** factor. The next two positions '00' denote the amount of **red**, the next two positions 'FF' denote the amount of **green** and the final two positions '00' denote the amount of **blue**.

### RGB

**RGB()** is used in expressions to set or evaluate the color properties of a chart object, where the color is defined by a red component **r**, a green component **g**, and a blue component **b** with values between 0 and 255.

#### Syntax:

```
RGB (r, g, b)
```

**Return data type:** dual

#### Arguments:

- **r, g, b**: Red, green, and blue component values. A color component of 0 corresponds to no contribution and one of 255 to full contribution.

*All arguments must be expressions that resolve to integers in the range 0 to 255.*

If interpreting the numeric component and formatting it in hexadecimal notation, the values of the color components are easier to see. For example, light green has the number 4 278 255 360, which in hexadecimal notation is FF00FF00. The first two positions 'FF' (255) denote the **alpha** factor. In the

functions **RGB** and **HSL**, this is always 'FF' (opaque). The next two positions '00' denote the amount of **red**, the next two positions 'FF' denote the amount of **green** and the final two positions '00' denote the amount of **blue**.

### HSL

**HSL()** is used in expressions to set or evaluate the color properties of a chart object, where the color is defined by values of **hue**, **saturation**, and **luminosity** between 0 and 1.

#### Syntax:

```
HSL (hue, saturation, luminosity)
```

**Return data type:** dual

#### Arguments:

- hue, saturation, luminosity: hue, saturation, and luminosity component values ranging between 0 and 1.

*All arguments must be expressions that resolve to integers in the range 0 to 1.*

If interpreting the numeric component and formatting it in hexadecimal notation, the RGB values of the color components are easier to see. For example, light green has the number 4 278 255 360, which in hexadecimal notation is FF00FF00 and RGB (0,255,0). This is equivalent to HSL (80/240, 240/240, 120/240) - a HSL value of (0.33, 1, 0.5).

## Conditional functions

The conditional functions all evaluate a condition and then return different answers depending on the condition value. The functions can be used in the load script and in chart expressions.

### Conditional functions overview

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

#### **alt**

The **alt** function returns the first of the parameters that has a valid number representation. If no such match is found, the last parameter will be returned. Any number of parameters can be used.

```
alt (case1 [, case2 , case3 , ...] , else)
```

#### **class**

The **class** function assigns the first parameter to a class interval. The result is a dual value with  $a \leq x < b$  as the textual value, where a and b are the upper and lower limits of the bin, and the lower bound as numeric value.

```
class (expression, interval [, label [, offset]])
```

### if

The **if** function returns a value depending on whether the condition provided with the function evaluates as True or False.

```
if (condition , then , else)
```

### match

The **match** function compares the first parameter with all the following ones and returns the number of the expression that matches. The comparison is case sensitive.

```
match (str, expr1 [, expr2,...exprN])
```

### mixmatch

The **mixmatch** function compares the first parameter with all the following ones and returns the number of the expression that matches. The comparison is case insensitive and insensitive to the Japanese Hiragana and Katakana character systems.

```
mixmatch (str, expr1 [, expr2,...exprN])
```

### pick

The pick function returns the *n*:th expression in the list.

```
pick (n, expr1[, expr2,...exprN])
```

### wildmatch

The **wildmatch** function compares the first parameter with all the following ones and returns the number of expression that matches. It permits the use of wildcard characters ( \* and ?) in the comparison strings. The comparison is case insensitive and insensitive to the Japanese Hiragana and Katakana character systems.

```
wildmatch (str, expr1 [, expr2,...exprN])
```

### alt

The **alt** function returns the first of the parameters that has a valid number representation. If no such match is found, the last parameter will be returned. Any number of parameters can be used.

#### Syntax:

```
alt(case1[, case2 , case3 , ...] , else)
```

The alt function is often used with number or date interpretation functions. This way, QlikView can test different date formats in a prioritized order. It can also be used to handle NULL values in numerical expressions.

### Examples and results:

Examples and results

| Example                                                                                                                                  | Result                                                                                                                                                                                                                                                                                                                                             |
|------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>alt( date#( dat , 'YYYY/MM/DD' ),       date#( dat , 'MM/DD/YYYY' ),       date#( dat , 'MM/DD/YY' ),       'No valid date' )</pre> | <p>This expression will test if the field date contains a date according to any of the three specified date formats. If so, it will return a dual value containing the original string and a valid number representation of a date. If no match is found, the text 'No valid date' will be returned (without any valid number representation).</p> |
| <pre>alt(Sales,0) + alt(Margin,0)</pre>                                                                                                  | <p>This expression adds the fields Sales and Margin, replacing any missing value (NULL) with a 0.</p>                                                                                                                                                                                                                                              |

### class

The **class** function assigns the first parameter to a class interval. The result is a dual value with  $a \leq x < b$  as the textual value, where a and b are the upper and lower limits of the bin, and the lower bound as numeric value.

#### Syntax:

```
class(expression, interval [, label [, offset]])
```

#### Arguments:

Class arguments

| Argument | Description                                                                                                                          |
|----------|--------------------------------------------------------------------------------------------------------------------------------------|
| interval | A number that specifies the bin width.                                                                                               |
| label    | An arbitrary string that can replace the 'x' in the result text.                                                                     |
| offset   | A number that can be used as offset from the default starting point of the classification. The default starting point is normally 0. |

### Examples and results:

Examples 1-3 and results

| Example                          | Result                                |
|----------------------------------|---------------------------------------|
| <pre>class( 23,10 )</pre>        | <p>returns '20&lt;=x&lt;30'</p>       |
| <pre>class( 23,5,'value' )</pre> | <p>returns '20&lt;= value &lt;25'</p> |
| <pre>class( 23,10,'x',5 )</pre>  | <p>returns '15&lt;=x&lt;25'</p>       |

In this example, we load a table containing name and age of people. We want to add a field that classifies each person according to an age group with a ten year interval. The source table looks like this:

## 9 Script syntax and chart functions

---

Source table

| Name  | Age |
|-------|-----|
| John  | 25  |
| Karen | 42  |
| Yoshi | 53  |

To add the age group classification field, you can add a preceding load statement using the **class** function. In this example, we load the source table using inline data.

```
LOAD *,
class(Age, 10, 'age') As Agegroup;
```

```
LOAD * INLINE
[Age, Name
25, John
42, Karen
53, Yoshi];
```

The resulting data that is loaded looks like this:

Results table

| Name  | Age | Agegroup       |
|-------|-----|----------------|
| John  | 25  | 20 <= age < 30 |
| Karen | 42  | 40 <= age < 50 |
| Yoshi | 53  | 50 <= age < 60 |

### if

The **if** function returns a value depending on whether the condition provided with the function evaluates as True or False.

#### Syntax:

```
if(condition , then [, else])
```

The if function has three parameters, *condition*, *then* and *else*, which are all expressions. The two other ones, *then* and *else*, can be of any type.

#### Arguments:

If arguments

| Argument  | Description                               |
|-----------|-------------------------------------------|
| condition | Expression that is interpreted logically. |

| Argument | Description                                                                                                                                                                                                                                                       |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| then     | Expression that can be of any type. If the <i>condition</i> is True, then the if function returns the value of the <i>then</i> expression.                                                                                                                        |
| else     | Expression that can be of any type. If the <i>condition</i> is False, then the if function returns the value of the <i>else</i> expression.<br><br>This parameter is optional. If the <i>condition</i> is False, NULL is returned if you have not specified else. |

### Examples and results:

| Examples and results                             |                                                                                                                                                         |
|--------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| Example                                          | Result                                                                                                                                                  |
| <code>if( Amount &gt;= 0, 'OK', 'Alarm' )</code> | This expression will test if the amount is a positive number (0 or larger) and return 'OK' if it is. If the amount is less than 0, 'Alarm' is returned. |

### match

The **match** function compares the first parameter with all the following ones and returns the number of the expression that matches. The comparison is case sensitive.

#### Syntax:

```
match(str, expr1 [, expr2, ...exprN])
```

*If you want to use case insensitive comparison, use the **mixmatch** function. If you want to use case insensitive comparison and wildcards, use the **wildmatch** function.*

### Examples and results:

| Examples and results                         |                                                         |
|----------------------------------------------|---------------------------------------------------------|
| Example                                      | Result                                                  |
| <code>match( M, 'Jan', 'Feb', 'Mar' )</code> | returns 2 if M = Feb.<br><br>returns 0 if M = Aprorjan. |

### mixmatch

The **mixmatch** function compares the first parameter with all the following ones and returns the number of the expression that matches. The comparison is case insensitive and insensitive to the Japanese Hiragana and Katakana character systems.

#### Syntax:

```
mixmatch(str, expr1 [, expr2, ...exprN])
```

If you want to use case sensitive comparison, use the **match** function. If you want to use case insensitive comparison and wildcards, use the **wildmatch** function.

### Examples and results:

#### Examples and results

| Example                                        | Result               |
|------------------------------------------------|----------------------|
| <code>mixmatch( M, 'Jan', 'Feb', 'Mar')</code> | returns 1 if M = jan |

### pick

The pick function returns the *n*:th expression in the list.

#### Syntax:

```
pick(n, expr1 [, expr2, ...exprN])
```

#### Arguments:

#### Pick arguments

| Argument | Description                             |
|----------|-----------------------------------------|
| <i>n</i> | <i>n</i> is an integer between 1 and N. |

### Examples and results:

#### Examples and results

| Example                                | Result                                     |
|----------------------------------------|--------------------------------------------|
| <code>pick( N, 'A', 'B', 4, 6 )</code> | returns 'B' if N = 2<br>returns 4 if N = 3 |

### wildmatch

The **wildmatch** function compares the first parameter with all the following ones and returns the number of expression that matches. It permits the use of wildcard characters ( \* and ?) in the comparison strings. The comparison is case insensitive and insensitive to the Japanese Hiragana and Katakana character systems.

#### Syntax:

```
wildmatch(str, expr1 [, expr2, ...exprN])
```

If you want to use comparison without wildcards, use the **match** or **mixmatch** functions. **match** has the best performance of the 3 functions.

### Examples and results:

#### Examples and results

| Example                                         | Result                                           |
|-------------------------------------------------|--------------------------------------------------|
| <code>wildmatch( M, 'ja*', 'fe?', 'mar')</code> | returns 1 if M = January<br>returns 2 if M = fex |

## Counter functions

This section describes functions related to record counters during **LOAD** statement evaluation in the load script. The only function that can be used in chart expressions is **RowNo()**.

Some counter functions do not have any parameters, but the trailing parentheses are however still required.

### Counter functions overview

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

#### **autonumber**

This script function returns a unique integer value for each distinct evaluated value of *expression* encountered during the script execution. This function can be used e.g. for creating a compact memory representation of a complex key.

```
autonumber (expression[, AutoID])
```

#### **autonumberhash128**

This script function calculates a 128-bit hash of the combined input expression values and the returns a unique integer value for each distinct hash value encountered during the script execution. This function can be used for example for creating a compact memory representation of a complex key.

```
autonumberhash128 (expression {, expression})
```

#### **autonumberhash256**

This script function calculates a 256-bit hash of the combined input expression values and returns a unique integer value for each distinct hash value encountered during the script execution. This function can be used e.g. for creating a compact memory representation of a complex key.

*This function is only available as a script function.*

```
autonumberhash256 (expression {, expression})
```

#### **fieldvaluecount**

This script function returns the number of distinct values in a field. *fieldname* must be given as a string (for example a quoted literal).

```
fieldvaluecount (fieldname)
```

### IterNo

This script function returns an integer indicating the current iteration within a **while** clause. The first iteration has number 1. The **IterNo** function is only meaningful if used together with a **while** clause.

```
IterNo ()
```

### RecNo

This script functions returns an integer for the number of the currently read row of the current table. The first record is number 1.

```
RecNo ()
```

### RowNo - script function

This function returns an integer for the position of the current row in the resulting QlikView internal table. The first row is number 1.

```
RowNo ()
```

### RowNo - chart function

**RowNo()** returns the number of the current row within the current column segment in a table. For bitmap charts, **RowNo()** returns the number of the current row within the chart's straight table equivalent.

```
RowNo ([TOTAL])
```

### autonumber

This script function returns a unique integer value for each distinct evaluated value of *expression* encountered during the script execution. This function can be used e.g. for creating a compact memory representation of a complex key.

*You can only connect **autonumber** keys that have been generated in the same data load, as the integer is generated according to the order the table is read. If you need to use keys that are persistent between data loads, independent of source data sorting, you should use the **hash128**, **hash160** or **hash256** functions.*

### Syntax:

```
autonumber (expression[, AutoID])
```

### Arguments:

#### Autonumber arguments

| Argument | Description                                                                                                                                                                                            |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AutoID   | In order to create multiple counter instances if the <b>autonumber</b> function is used on different keys within the script, the optional parameter <i>AutoID</i> can be used for naming each counter. |

### Example: Creating a composite key

In this example we create a composite key using the **autonumber** function to conserve memory. The example is brief for demonstration purpose, but would be meaningful with a table containing a large number of rows.

Composite key example 1

| Region | Year | Month | Sales |
|--------|------|-------|-------|
| North  | 2014 | May   | 245   |
| North  | 2014 | May   | 347   |
| North  | 2014 | June  | 127   |
| South  | 2014 | June  | 645   |
| South  | 2013 | May   | 367   |
| South  | 2013 | May   | 221   |

The source data is loaded using inline data. Then we add a preceding load which creates a composite key from the Region, Year and Month fields.

```
RegionSales:
LOAD *,
AutoNumber(Region&Year&Month) as RYMkey;

LOAD * INLINE
[Region, Year, Month, Sales
North, 2014, May, 245
North, 2014, May, 347
North, 2014, June, 127
South, 2014, June, 645
South, 2013, May, 367
South, 2013, May, 221
];
```

The resulting table looks like this:

Composite key example 2

| Region | Year | Month | Sales | RYMkey |
|--------|------|-------|-------|--------|
| North  | 2014 | May   | 245   | 1      |
| North  | 2014 | May   | 347   | 1      |
| North  | 2014 | June  | 127   | 2      |
| South  | 2014 | June  | 645   | 3      |
| South  | 2013 | May   | 367   | 4      |
| South  | 2013 | May   | 221   | 4      |

## 9 Script syntax and chart functions

In this example you can refer to the RYMkey, for example 1, instead of the string 'North2014May' if you need to link to another table.

Now we load a source table of costs in a similar way. The Region, Year and Month fields are excluded in the preceding load to avoid creating a synthetic key, we are already creating a composite key with the **autonumber** function, linking the tables.

```
RegionCosts:
LOAD Costs,
AutoNumber(Region&Year&Month) as RYMkey;
```

```
LOAD * INLINE
[Region, Year, Month, Costs
South, 2013, May, 167
North, 2014, May, 56
North, 2014, June, 199
South, 2014, June, 64
South, 2013, May, 172
South, 2013, May, 126
];
```

Now we can add a table chart to a sheet, and add the Region, Year and Month fields, as well as Sum measures for the sales and the costs. the table will look like this:

Composite key example 3

| Region | Year | Month | Sum([Sales]) | Sum([Costs]) |
|--------|------|-------|--------------|--------------|
| Totals | -    | -     | 1952         | 784          |
| North  | 2014 | June  | 127          | 199          |
| North  | 2014 | May   | 592          | 56           |
| South  | 2014 | June  | 645          | 64           |
| South  | 2013 | May   | 588          | 465          |

### autonumberhash128

This script function calculates a 128-bit hash of the combined input expression values and the returns a unique integer value for each distinct hash value encountered during the script execution. This function can be used for example for creating a compact memory representation of a complex key.

*You can only connect **autonumberhash128** keys that have been generated in the same data load, as the integer is generated according to the order the table is read. If you need to use keys that are persistent between data loads, independent of source data sorting, you should use the **hash128**, **hash160** or **hash256** functions.*

#### Syntax:

```
autonumberhash128 (expression {, expression})
```

### Example: Creating a composite key

In this example we create a composite key using the **autonumberhash128** function to conserve memory. The example is brief for demonstration purpose, but would be meaningful with a table containing a large number of rows.

Composite key example 1

| Region | Year | Month | Sales |
|--------|------|-------|-------|
| North  | 2014 | May   | 245   |
| North  | 2014 | May   | 347   |
| North  | 2014 | June  | 127   |
| South  | 2014 | June  | 645   |
| South  | 2013 | May   | 367   |
| South  | 2013 | May   | 221   |

The source data is loaded using inline data. Then we add a preceding load which creates a composite key from the Region, Year and Month fields.

```
RegionSales:
LOAD *,
AutoNumberHash128(Region, Year, Month) as RYMkey;

LOAD * INLINE
[Region, Year, Month, Sales
North, 2014, May, 245
North, 2014, May, 347
North, 2014, June, 127
South, 2014, June, 645
South, 2013, May, 367
South, 2013, May, 221
];
```

The resulting table looks like this:

Composite key example 2

| Region | Year | Month | Sales | RYMkey |
|--------|------|-------|-------|--------|
| North  | 2014 | May   | 245   | 1      |
| North  | 2014 | May   | 347   | 1      |
| North  | 2014 | June  | 127   | 2      |
| South  | 2014 | June  | 645   | 3      |
| South  | 2013 | May   | 367   | 4      |
| South  | 2013 | May   | 221   | 4      |

## 9 Script syntax and chart functions

In this example you can refer to the RYMkey, for example 1, instead of the string 'North2014May' if you need to link to another table.

Now we load a source table of costs in a similar way. The Region, Year and Month fields are excluded in the preceding load to avoid creating a synthetic key, we are already creating a composite key with the **autonumberhash128** function, linking the tables.

```
RegionCosts:
LOAD Costs,
AutoNumberHash128(Region, Year, Month) as RYMkey;
```

```
LOAD * INLINE
[Region, Year, Month, Costs
South, 2013, May, 167
North, 2014, May, 56
North, 2014, June, 199
South, 2014, June, 64
South, 2013, May, 172
South, 2013, May, 126
];
```

Now we can add a table chart to a sheet, and add the Region, Year and Month fields, as well as Sum measures for the sales and the costs. the table will look like this:

Composite key example 3

| Region | Year | Month | Sum([Sales]) | Sum([Costs]) |
|--------|------|-------|--------------|--------------|
| Totals | -    | -     | 1952         | 784          |
| North  | 2014 | June  | 127          | 199          |
| North  | 2014 | May   | 592          | 56           |
| South  | 2014 | June  | 645          | 64           |
| South  | 2013 | May   | 588          | 465          |

### autonumberhash256

This script function calculates a 256-bit hash of the combined input expression values and returns a unique integer value for each distinct hash value encountered during the script execution. This function can be used e.g. for creating a compact memory representation of a complex key.

*You can only connect **autonumberhash256** keys that have been generated in the same data load, as the integer is generated according to the order the table is read. If you need to use keys that are persistent between data loads, independent of source data sorting, you should use the **hash128**, **hash160** or **hash256** functions.*

#### Syntax:

```
autonumberhash256 (expression {, expression})
```

### Example: Creating a composite key

In this example we create a composite key using the **autonumberhash256** function to conserve memory. The example is brief for demonstration purpose, but would be meaningful with a table containing a large number of rows.

Composite key example 1

| Region | Year | Month | Sales |
|--------|------|-------|-------|
| North  | 2014 | May   | 245   |
| North  | 2014 | May   | 347   |
| North  | 2014 | June  | 127   |
| South  | 2014 | June  | 645   |
| South  | 2013 | May   | 367   |
| South  | 2013 | May   | 221   |

The source data is loaded using inline data. Then we add a preceding load which creates a composite key from the Region, Year and Month fields.

```
RegionSales:
LOAD *,
AutoNumberHash256(Region, Year, Month) as RYMkey;

LOAD * INLINE
[Region, Year, Month, Sales
North, 2014, May, 245
North, 2014, May, 347
North, 2014, June, 127
South, 2014, June, 645
South, 2013, May, 367
South, 2013, May, 221
];
```

The resulting table looks like this:

Composite key example 2

| Region | Year | Month | Sales | RYMkey |
|--------|------|-------|-------|--------|
| North  | 2014 | May   | 245   | 1      |
| North  | 2014 | May   | 347   | 1      |
| North  | 2014 | June  | 127   | 2      |
| South  | 2014 | June  | 645   | 3      |
| South  | 2013 | May   | 367   | 4      |
| South  | 2013 | May   | 221   | 4      |

## 9 Script syntax and chart functions

---

In this example you can refer to the RYMkey, for example 1, instead of the string 'North2014May' if you need to link to another table.

Now we load a source table of costs in a similar way. The Region, Year and Month fields are excluded in the preceding load to avoid creating a synthetic key, we are already creating a composite key with the **autonumberhash256** function, linking the tables.

```
RegionCosts:
LOAD Costs,
AutoNumberHash256(Region, Year, Month) as RYMkey;
```

```
LOAD * INLINE
[Region, Year, Month, Costs
South, 2013, May, 167
North, 2014, May, 56
North, 2014, June, 199
South, 2014, June, 64
South, 2013, May, 172
South, 2013, May, 126
];
```

Now we can add a table chart to a sheet, and add the Region, Year and Month fields, as well as Sum measures for the sales and the costs. the table will look like this:

Composite key example 3

| Region | Year | Month | Sum([Sales]) | Sum([Costs]) |
|--------|------|-------|--------------|--------------|
| Totals | -    | -     | 1952         | 784          |
| North  | 2014 | June  | 127          | 199          |
| North  | 2014 | May   | 592          | 56           |
| South  | 2014 | June  | 645          | 64           |
| South  | 2013 | May   | 588          | 465          |

### fieldvaluecount

This script function returns the number of distinct values in a field. *fieldname* must be given as a string (for example a quoted literal).

#### Syntax:

```
fieldvaluecount(fieldname)
```

#### Example:

In this example the number of regions is counted and stored in the RegionCount variable. This value, 2 in this case, can then be used for further transformations where you need to know the number of existing regions.

```
LOAD * INLINE
[Region, Year, Month, Sales
South, 2014, June, 645
```

```
North, 2014, May, 245
North, 2014, May, 347
North, 2014, June, 127
South, 2013, May, 367
South, 2013, July, 221];
```

```
Let RegionCount = FieldValueCount('Region');
```

### IterNo

This script function returns an integer indicating the current iteration within a **while** clause. The first iteration has number 1. The **IterNo** function is only meaningful if used together with a **while** clause.

#### Syntax:

```
IterNo ()
```

#### Examples and results:

```
LOAD
 IterNo() as Day,
 Date(StartDate + IterNo() - 1) as Date
 while StartDate + IterNo() - 1 <= EndDate;
```

```
LOAD * INLINE
[StartDate, EndDate
2014-01-22, 2014-01-26
];
```

This **LOAD** statement will generate one record per date within the range defined by **StartDate** and **EndDate**.

In this example, the resulting table will look like this:

Results table

| Day | Date       |
|-----|------------|
| 1   | 2014-01-22 |
| 2   | 2014-01-23 |
| 3   | 2014-01-24 |
| 4   | 2014-01-25 |
| 5   | 2014-01-26 |

### RecNo

This script functions returns an integer for the number of the currently read row of the current table. The first record is number 1.

#### Syntax:

```
RecNo ()
```

In contrast to **RowNo()**, which counts rows in the resulting QlikView table, **RecNo()**, counts the records in the raw data table and is reset when a raw data table is concatenated to another.

### Example: Load script

Raw data table load:

```
Tab1:
LOAD * INLINE
[A, B
1, aa
2, cc
3, ee];
```

```
Tab2:
LOAD * INLINE
[C, D
5, xx
4, yy
6, zz];
```

Loading record and row numbers for selected rows:

```
QTab:
LOAD *,
RecNo(),
RowNo()
resident Tab1 where A<>2;

LOAD
C as A,
D as B,
RecNo(),
RowNo()
resident Tab2 where A<>5;
```

```
//we don't need the source tables anymore, so we drop them
Drop tables Tab1, Tab2;
```

The resulting QlikView internal table:

Results table

| A | B  | RecNo() | RowNo() |
|---|----|---------|---------|
| 1 | aa | 1       | 1       |
| 3 | ee | 3       | 2       |
| 4 | yy | 2       | 3       |
| 6 | zz | 3       | 4       |

### RowNo

This function returns an integer for the position of the current row in the resulting QlikView internal table. The first row is number 1.

### Syntax:

**RowNo** ( [TOTAL] )

In contrast to **RecNo**( ), which counts the records in the raw data table, the **RowNo**( ) function does not count records that are excluded by **where** clauses and is not reset when a raw data table is concatenated to another.

*If you use preceding load, that is, a number of stacked **LOAD** statements reading from the same table, you can only use **RowNo**( ) in the top **LOAD** statement. If you use **RowNo**( ) in subsequent **LOAD** statements, 0 is returned.*

### Example: Load script

Raw data table load:

```
Tab1:
LOAD * INLINE
[A, B
1, aa
2, cc
3, ee];
```

```
Tab2:
LOAD * INLINE
[C, D
5, xx
4, yy
6, zz];
```

Loading record and row numbers for selected rows:

```
QTab:
LOAD *,
RecNo(),
RowNo()
resident Tab1 where A<>2;
```

```
LOAD
C as A,
D as B,
RecNo(),
RowNo()
resident Tab2 where A<>5;
```

```
//We don't need the source tables anymore, so we drop them
Drop tables Tab1, Tab2;
```

The resulting QlikView internal table:

Results table

| A | B  | RecNo( ) | RowNo( ) |
|---|----|----------|----------|
| 1 | aa | 1        | 1        |
| 3 | ee | 3        | 2        |
| 4 | yy | 2        | 3        |
| 6 | zz | 3        | 4        |

### RowNo

**RowNo()** returns the number of the current row within the current column segment in a table. For bitmap charts, **RowNo()** returns the number of the current row within the chart's straight table equivalent.

If the table or table equivalent has multiple vertical dimensions, the current column segment will include only rows with the same values as the current row in all dimension columns, except for the column showing the last dimension in the inter-field sort order.

Sorting on y-values in charts or sorting by expression columns in tables is not allowed when this chart function is used in any of the chart's expressions. These sort alternatives are therefore automatically disabled. When you use this chart function in a visualization or table, the sorting of the visualization will revert back to the sorted input to this function.

#### Syntax:

```
RowNo ([TOTAL])
```

**Return data type:** integer

#### Arguments:

- **TOTAL:** If the table is one-dimensional or if the qualifier **TOTAL** is used as argument, the current column segment is always equal to the entire column. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

#### Examples:

Examples and results

| Example                                                                                                                                                                                                         | Result                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Create a chart consisting of a table with the dimensions <b>Customer</b> , <b>UnitSales</b> , and add <b>RowNo( )</b> and <b>RowNo(TOTAL)</b> as measures labeled <b>Row in Segment</b> and <b>Row Number</b> . | <p>The <b>Row in Segment</b> column shows the results 1,2,3 for the column segment containing the values of UnitSales for customer Astrida. The row numbering then begins at 1 again for the next column segment, which is Betacab.</p> <p>The <b>Row Number</b> column disregards the dimensions can be used to count the rows in the table.</p> |

## 9 Script syntax and chart functions

| Example                                                                                                 | Result                                                                                                                                                |
|---------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| Add the expression:<br><code>IF( RowNo( )=1, 0, UnitSales / Above( UnitSales ))</code><br>as a measure. | This expression returns 0 for the first row in each column segment, so the column will show:<br><br>0, 2.25, 1.1111111, 0, 2.5, 5, 0, NULL, 0, and 4. |

### Data used in examples:

```
Temp:
LOAD * inline [
Customer|Product|OrderNumber|UnitSales|UnitPrice
Astrida|AA|1|4|16
Astrida|AA|7|10|15
Astrida|BB|4|9|9
Betacab|CC|6|5|10
Betacab|AA|5|2|20
Betacab|BB|1|25| 25
Canutility|AA|3|8|15
Canutility|CC|||19
Divadip|CC|2|4|16
Divadip|DD|3|1|25
] (delimiter is '|');
```

Example data in table form

| Customer   | UnitSales | Row in Segment | Row Number |
|------------|-----------|----------------|------------|
| Astrida    | 4         | 1              | 1          |
| Astrida    | 10        | 2              | 2          |
| Astrida    | 9         | 3              | 3          |
| Betacab    | 5         | 1              | 4          |
| Betacab    | 2         | 2              | 5          |
| Betacab    | 25        | 3              | 6          |
| Canutility | 8         | 1              | 7          |
| Canutility | -         | 2              | 8          |
| Divadip    | 4         | 1              | 9          |
| Divadip    | 1         | 2              | 10         |

## Date and time functions

QlikView date and time functions are used to transform and convert date and time values. All functions can be used in both the load script and in chart expressions.

Functions are based on a date-time serial number that equals the number of days since December 30, 1899. The integer value represents the day and the fractional value represents the time of the day.

QlikView uses the numerical value of the parameter, so a number is valid as a parameter also when it is not formatted as a date or a time. If the parameter does not correspond to numerical value, for example, because it is a string, then QlikView attempts to interpret the string according to the date and time environment variables.

If the time format used in the parameter does not correspond to the one set in the environment variables, QlikView will not be able to make a correct interpretation. To resolve this, either change the settings or use an interpretation function.

In the examples for each function, the default time and date formats hh:mm:ss and YYYY-MM-DD (ISO 8601) are assumed.

*When processing a timestamp with a date or time function, QlikView ignores any daylight savings time parameters unless the date or time function includes a geographical position.*

*For example, `convertToLocalTime( filetime('Time.qvd'), 'Paris')` would use daylight savings time parameters while `convertToLocalTime(filetime('Time.qvd'), 'GMT-01:00')` would not use daylight savings time parameters.*

### Date and time functions overview

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

#### Integer expressions of time

##### **second**

This function returns an integer representing the second when the fraction of the **expression** is interpreted as a time according to the standard number interpretation.

```
second (expression)
```

##### **minute**

This function returns an integer representing the minute when the fraction of the **expression** is interpreted as a time according to the standard number interpretation.

```
minute (expression)
```

##### **hour**

This function returns an integer representing the hour when the fraction of the **expression** is interpreted as a time according to the standard number interpretation.

```
hour (expression)
```

##### **day**

This function returns an integer representing the day when the fraction of the **expression** is interpreted as a date according to the standard number interpretation.

```
day (expression)
```

### week

This function returns an integer representing the week number according to ISO 8601. The week number is calculated from the date interpretation of the expression, according to the standard number interpretation.

```
week (timestamp [, first_week_day [, broken_weeks [, reference_day]])
```

### month

This function returns a dual value with a month name as defined in the environment variable **MonthNames** and an integer between 1-12. The month is calculated from the date interpretation of the expression, according to the standard number interpretation.

```
month (expression)
```

### year

This function returns an integer representing the year when the **expression** is interpreted as a date according to the standard number interpretation.

```
year (expression)
```

### weekyear

This function returns the year to which the week number belongs according to ISO 8601. The week number ranges between 1 and approximately 52.

```
weekyear (expression)
```

### weekday

This function returns a dual value with: A day name as defined in the environment variable **DayNames**. An integer between 0-6 corresponding to the nominal day of the week (0-6).

```
weekday (date)
```

## Timestamp functions

### now

This function returns a timestamp of the current time from the system clock. The default value is 1.

```
now ([timer_mode])
```

### today

This function returns the current date from the system clock.

```
today ([timer_mode])
```

### LocalTime

This function returns a timestamp of the current time from the system clock for a specified time zone.

```
localtime ([timezone [, ignoreDST]])
```

## Make functions

### makedate

This function returns a date calculated from the year **YYYY**, the month **MM** and the day **DD**.

```
makedate (YYYY [, MM [, DD]])
```

### **makeweekdate**

This function returns a date calculated from the year **YYYY**, the week **WW** and the day-of-week **D**.

```
makeweekdate (YYYY [, WW [, D]])
```

### **maketime**

This function returns a time calculated from the hour **hh**, the minute **mm**, and the second **ss**.

```
maketime (hh [, mm [, ss [.fff]]])
```

### Other date functions

#### **AddMonths**

This function returns the date occurring **n** months after **startdate** or, if **n** is negative, the date occurring **n** months before **startdate**.

```
addmonths (startdate, n , [, mode])
```

#### **AddYears**

This function returns the date occurring **n** years after **startdate** or, if **n** is negative, the date occurring **n** years before **startdate**.

```
addyears (startdate, n)
```

#### **yeartodate**

This function finds if the input date falls within the year of the date the script was last loaded, and returns True if it does, False if it does not.

```
yeartodate (timestamp [, yearoffset [, firstmonth [, todaydate]]])
```

### Timezone functions

#### **timezone**

This function returns the name of the current time zone, as defined in Windows, not taking into account the daylight savings adjustment.

```
timezone ()
```

#### **GMT**

This function returns the date and current Greenwich Mean Time, as derived from the system clock and Windows time settings.

```
GMT ()
```

#### **UTC**

Returns the date and current Coordinated Universal Time.

```
UTC ()
```

#### **daylightsaving**

Returns the current adjustment for daylight saving time, as defined in Windows.

```
daylightsaving ()
```

### converttolocaltime

Converts a UTC or GMT timestamp to local time as a dual value. The place can be any of a number of cities and time zones around the world.

```
converttolocaltime (timestamp [, place [, ignore_dst=false]])
```

### Set time functions

#### setdateyear

This function takes as input a **timestamp** and a **year** and updates the **timestamp** with the **year** specified in input.

```
setdateyear (timestamp, year)
```

#### setdateyearmonth

This function takes as input a **timestamp**, a **month** and a **year** and updates the **timestamp** with the **year** and the **month** specified in input.

```
setdateyearmonth (timestamp, year, month)
```

### In... functions

#### inyear

This function returns True if **timestamp** lies inside the year containing **base\_date**.

```
inyear (date, basedate , shift [, first_month_of_year = 1])
```

#### inyeartodate

This function returns True if **timestamp** lies inside the part of year containing **base\_date** up until and including the last millisecond of **base\_date**.

```
inyeartodate (date, basedate , shift [, first_month_of_year = 1])
```

#### inquarter

This function returns True if **timestamp** lies inside the quarter containing **base\_date**.

```
inquarter (date, basedate , shift [, first_month_of_year = 1])
```

#### inquartertodate

This function returns True if **timestamp** lies inside the part of the quarter containing **base\_date** up until and including the last millisecond of **base\_date**.

```
inquartertodate (date, basedate , shift [, first_month_of_year = 1])
```

#### inmonth

This function returns True if **timestamp** lies inside the month containing **base\_date**.

```
inmonth (date, basedate , shift)
```

### **inmonthtodate**

Returns True if **timestamp** lies inside the part of month containing **base\_date** up until and including the last millisecond of **base\_date**.

```
inmonthtodate (date, basedate , shift)
```

### **inmonths**

This function finds if a timestamp falls within the same month, bi-month, quarter, four-month period, or half-year as a base date. It is also possible to find if the timestamp falls within a previous or following time period.

```
inmonths (n, date, basedate , shift [, first_month_of_year = 1])
```

### **inmonthstodate**

This function finds if a timestamp falls within the part of a period of the month, bi-month, quarter, four-month period, or half-year up to and including the last millisecond of **base\_date**. It is also possible to find if the timestamp falls within a previous or following time period.

```
inmonthstodate (n, date, basedate , shift [, first_month_of_year = 1])
```

### **inweek**

This function returns True if **timestamp** lies inside the week containing **base\_date**.

```
inweek (date, basedate , shift [, weekstart])
```

### **inweektodate**

This function returns True if **timestamp** lies inside the part of week containing **base\_date** up until and including the last millisecond of **base\_date**.

```
inweektodate (date, basedate , shift [, weekstart])
```

### **inlunarweek**

This function returns true if **timestamp** lies inside the lunar week containing **base\_date**. Lunar weeks in QlikView are defined by counting 1 January as the first day of the week.

```
inlunarweek (date, basedate , shift [, weekstart])
```

### **inlunarweektodate**

This function returns true if **timestamp** lies inside the part of the lunar week up to and including the last millisecond of **base\_date**. Lunar weeks in QlikView are defined by counting 1 January as the first day of the week.

```
inlunarweektodate (date, basedate , shift [, weekstart])
```

### **inday**

This function returns True if **timestamp** lies inside the day containing **base\_timestamp**.

```
inday (timestamp, basetimestamp , shift [, daystart])
```

### indaytotime

This function returns True if **timestamp** lies inside the part of day containing **base\_timestamp** up until and including the exact millisecond of **base\_timestamp**.

```
indaytotime (timestamp, basetimestamp , shift [, daystart])
```

### Start ... end functions

#### yearstart

This function returns a timestamp corresponding to the start of the first day of the year containing **date**. The default output format will be the **DateFormat** set in the script.

```
yearstart (date [, shift = 0 [, first_month_of_year = 1]])
```

#### yearend

This function returns a value corresponding to a timestamp of the last millisecond of the last day of the year containing **date**. The default output format will be the **DateFormat** set in the script.

```
yearend (date [, shift = 0 [, first_month_of_year = 1]])
```

#### yearname

This function returns a four-digit year as display value with an underlying numeric value corresponding to a timestamp of the first millisecond of the first day of the year containing **date**.

```
yearname (date [, shift = 0 [, first_month_of_year = 1]])
```

#### quarterstart

This function returns a value corresponding to a timestamp of the first millisecond of the quarter containing **date**. The default output format will be the **DateFormat** set in the script.

```
quarterstart (date [, shift = 0 [, first_month_of_year = 1]])
```

#### quarterend

This function returns a value corresponding to a timestamp of the last millisecond of the quarter containing **date**. The default output format will be the **DateFormat** set in the script.

```
quarterend (date [, shift = 0 [, first_month_of_year = 1]])
```

#### quartername

This function returns a display value showing the months of the quarter (formatted according to the **MonthNames** script variable) and year with an underlying numeric value corresponding to a timestamp of the first millisecond of the first day of the quarter.

```
quartername (date [, shift = 0 [, first_month_of_year = 1]])
```

#### monthstart

This function returns a value corresponding to a timestamp of the first millisecond of the first day of the month containing **date**. The default output format will be the **DateFormat** set in the script.

```
monthstart (date [, shift = 0])
```

### monthend

This function returns a value corresponding to a timestamp of the last millisecond of the last day of the month containing **date**. The default output format will be the **DateFormat** set in the script.

```
monthend (date [, shift = 0])
```

### monthname

This function returns a display value showing the month (formatted according to the **MonthNames** script variable) and year with an underlying numeric value corresponding to a timestamp of the first millisecond of the first day of the month.

```
monthname (date [, shift = 0])
```

### monthsstart

This function returns a value corresponding to the timestamp of the first millisecond of the month, bi-month, quarter, four-month period, or half-year containing a base date. It is also possible to find the timestamp for a previous or following time period.

```
monthsstart (n, date [, shift = 0 [, first_month_of_year = 1]])
```

### monthsend

This function returns a value corresponding to a timestamp of the last millisecond of the month, bi-month, quarter, four-month period, or half-year containing a base date. It is also possible to find the timestamp for a previous or following time period.

```
monthsend (n, date [, shift = 0 [, first_month_of_year = 1]])
```

### monthsname

This function returns a display value representing the range of the months of the period (formatted according to the **MonthNames** script variable) as well as the year. The underlying numeric value corresponds to a timestamp of the first millisecond of the month, bi-month, quarter, four-month period, or half-year containing a base date.

```
monthsname (n, date [, shift = 0 [, first_month_of_year = 1]])
```

### weekstart

This function returns a value corresponding to a timestamp of the first millisecond of the first day (Monday) of the calendar week containing **date**. The default output format is the **DateFormat** set in the script.

```
weekstart (date [, shift = 0 [, weekoffset = 0]])
```

### weekend

This function returns a value corresponding to a timestamp of the last millisecond of the last day (Sunday) of the calendar week containing **date**. The default output format will be the **DateFormat** set in the script.

```
weekend (date [, shift = 0 [, weekoffset = 0]])
```

### weekname

This function returns a value showing the year and week number with an underlying numeric value corresponding to a timestamp of the first millisecond of the first day of the week containing **date**.

```
weekname (date [, shift = 0 [, weekoffset = 0]])
```

### **lunarweekstart**

This function returns a value corresponding to a timestamp of the first millisecond of the lunar week containing **date**. Lunar weeks in QlikView are defined by counting 1 January as the first day of the week.

```
lunarweekstart (date [, shift = 0 [, weekoffset = 0]])
```

### **lunarweekend**

This function returns a value corresponding to a timestamp of the last millisecond of the lunar week containing **date**. Lunar weeks in QlikView are defined by counting 1 January as the first day of the week.

```
lunarweekend (date [, shift = 0 [, weekoffset = 0]])
```

### **lunarweekname**

This function returns a display value showing the year and lunar week number corresponding to a timestamp of the first millisecond of the first day of the lunar week containing **date**. Lunar weeks in QlikView are defined by counting 1 January as the first day of the week.

```
lunarweekname (date [, shift = 0 [, weekoffset = 0]])
```

### **daystart**

This function returns a value corresponding to a timestamp with the first millisecond of the day contained in the **time** argument. The default output format will be the **TimestampFormat** set in the script.

```
daystart (timestamp [, shift = 0 [, dayoffset = 0]])
```

### **dayend**

This function returns a value corresponding to a timestamp of the final millisecond of the day contained in **time**. The default output format will be the **TimestampFormat** set in the script.

```
dayend (timestamp [, shift = 0 [, dayoffset = 0]])
```

### **dayname**

This function returns a value showing the date with an underlying numeric value corresponding to a timestamp of the first millisecond of the day containing **time**.

```
dayname (timestamp [, shift = 0 [, dayoffset = 0]])
```

## Day numbering functions

### **age**

The **age** function returns the age at the time of **timestamp** (in completed years) of somebody born on **date\_of\_birth**.

```
age (timestamp, date_of_birth)
```

### **networkdays**

The **networkdays** function returns the number of working days (Monday-Friday) between and including **start\_date** and **end\_date** taking into account any optionally listed **holiday**.

```
networkdays (start:date, end_date {, holiday})
```

### firstworkdate

The **firstworkdate** function returns the latest starting date to achieve **no\_of\_workdays** (Monday-Friday) ending no later than **end\_date** taking into account any optionally listed holidays. **end\_date** and **holiday** should be valid dates or timestamps.

```
firstworkdate (end_date, no_of_workdays {, holiday})
```

### lastworkdate

The **lastworkdate** function returns the earliest ending date to achieve **no\_of\_workdays** (Monday-Friday) if starting at **start\_date** taking into account any optionally listed **holiday**. **start\_date** and **holiday** should be valid dates or timestamps.

```
lastworkdate (start_date, no_of_workdays {, holiday})
```

### daynumberofyear

This function calculates the day number of the year in which a timestamp falls. The calculation is made from the first millisecond of the first day of the year, but the first month can be offset.

```
daynumberofyear (date[, firstmonth])
```

### daynumberofquarter

This function calculates the day number of the quarter in which a timestamp falls.

```
daynumberofquarter (date[, firstmonth])
```

### addmonths

This function returns the date occurring **n** months after **startdate** or, if **n** is negative, the date occurring **n** months before **startdate**.

#### Syntax:

```
AddMonths (startdate, n , [, mode])
```

**Return data type:** dual

#### Arguments:

AddMonths arguments

| Argument  | Description                                                                                                                                                                                                                                                                                                            |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| startdate | The start date as a time stamp, for example '2012-10-12'.                                                                                                                                                                                                                                                              |
| n         | Number of months as a positive or negative integer.                                                                                                                                                                                                                                                                    |
| mode      | <b>mode</b> specifies if the month is added relative to the beginning of the month or relative to the end of the month. If the input date is the 28th or above and <b>mode</b> is set to 1, the function will return a date which is the same distance from the end of the month as the input date. Default mode is 0. |

### Examples and results:

Examples and results

| Example                                     | Result               |
|---------------------------------------------|----------------------|
| <code>addmonths ('2003-01-29', 3)</code>    | returns '2003-04-29' |
| <code>addmonths ('2003-01-29', 3, 0)</code> | returns '2003-04-29' |
| <code>addmonths ('2003-01-29', 3, 1)</code> | returns '2003-04-28' |
| <code>addmonths ('2003-01-29', 1, 0)</code> | returns '2003-02-28' |
| <code>addmonths ('2003-01-29', 1, 1)</code> | returns '2003-02-26' |
| <code>addmonths ('2003-02-28', 1, 0)</code> | returns '2003-03-28' |
| <code>addmonths ('2003-02-28', 1, 1)</code> | returns '2003-03-31' |

### addyears

This function returns the date occurring **n** years after **startdate** or, if **n** is negative, the date occurring **n** years before **startdate**.

#### Syntax:

```
AddYears (startdate, n)
```

**Return data type:** dual

#### Arguments:

AddYears arguments

| Argument               | Description                                               |
|------------------------|-----------------------------------------------------------|
| <code>startdate</code> | The start date as a time stamp, for example '2012-10-12'. |
| <code>n</code>         | Number of years as a positive or negative integer.        |

### Examples and results:

Examples and results

| Example                                  | Result               |
|------------------------------------------|----------------------|
| <code>addyears ('2010-01-29', 3)</code>  | returns '2013-01-29' |
| <code>addyears ('2010-01-29', -1)</code> | returns '2009-01-29' |

### age

The **age** function returns the age at the time of **timestamp** (in completed years) of somebody born on **date\_of\_birth**.

### Syntax:

```
age(timestamp, date_of_birth)
```

Can be an expression.

**Return data type:** numeric

### Arguments:

#### Age arguments

| Argument      | Description                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------------|
| timestamp     | The timestamp, or expression resolving to a timestamp, up to which to calculate the completed number of years. |
| date_of_birth | Date of birth of the person whose age is being calculated. Can be an expression.                               |

### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

#### Example 1:

```
age('25/01/2014', '29/10/2012')
```

Returns 1.

#### Example 2:

```
age('29/10/2014', '29/10/2012')
```

Returns 2.

#### Example 3:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
Employees :
LOAD * INLINE [
Member|DateOfBirth
John|28/03/1989
Linda|10/12/1990
Steve|5/2/1992
Birg|31/3/1993
Raj|19/5/1994
Prita|15/9/1994
Su|11/12/1994
Goran|2/3/1995
Sunny|14/5/1996
Ajoa|13/6/1996
Daphne|7/7/1998
```

```

Biffy|4/8/2000
] (delimiter is |);
AgeTable:
Load *,
age('20/08/2015', DateOfBirth) AS Age
Resident Employees;
Drop table Employees;

```

The resulting table shows the returned values of age for each of the records in the table.

Example 3 results

| Member | DateOfBirth | Age |
|--------|-------------|-----|
| John   | 28/03/1989  | 26  |
| Linda  | 10/12/1990  | 24  |
| Steve  | 5/2/1992    | 23  |
| Birg   | 31/3/1993   | 22  |
| Raj    | 19/5/1994   | 21  |
| Prita  | 15/9/1994   | 20  |
| Su     | 11/12/1994  | 20  |
| Goran  | 2/3/1995    | 20  |
| Sunny  | 14/5/1996   | 19  |
| Ajoa   | 13/6/1996   | 19  |
| Daphne | 7/7/1998    | 17  |
| Biffy  | 4/8/2000    | 15  |

### converttolocaltime

Converts a UTC or GMT timestamp to local time as a dual value.

#### Syntax:

```
ConvertToLocalTime(timestamp [, place [, ignore_dst=false]])
```

**Return data type:** dual

ConvertToLocalTime arguments

| Argument         | Description                                                                                                       |
|------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>timestamp</b> | The date to evaluate as a timestamp or expression resolving to a timestamp, to convert, for example '2012-10-12'. |

| Argument          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>place</b>      | <p>A place or timezone from the table of places and timezones below. Alternatively, you can use GMT or UTC to define the local time. The following values and time offset ranges are valid:</p> <ul style="list-style-type: none"> <li>• GMT</li> <li>• GMT-12:00 - GMT-01:00</li> <li>• GMT+01:00 - GMT+14:00</li> <li>• UTC</li> <li>• UTC-12:00 - UTC-01:00</li> <li>• UTC+01:00 - UTC+14:00</li> </ul> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> <p> <i>If you use a DST offset (that is, you specify an <b>ignore_dst</b> argument value evaluating to False), you must specify a place, rather than a GMT offset, in the <b>place</b> argument. This is because adjusting for Daylight Saving Time requires latitudinal information in addition to the longitudinal information provided by a GMT offset. For information, see <a href="#">Using GMT offsets in combination with DST</a> (page 1266).</i></p> </div> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> <p> <i>You can only use standard time offsets. It's not possible to use an arbitrary time offset, for example, GMT-04:27.</i></p> </div> |
| <b>ignore_dst</b> | <p>If this argument evaluates to True, DST (daylight saving time) is ignored. Valid argument values evaluating to True include -1 and True().</p> <p>If this argument evaluates to False, the timestamp is adjusted for daylight saving time. Valid argument values evaluating to False include 0 and False().</p> <p>If the <b>ignore_dst</b> argument value is invalid, the function evaluates the expression as if the <b>ignore_dst</b> value evaluates to True. If the <b>ignore_dst</b> argument value is not specified, the function evaluates the expression as if the <b>ignore_dst</b> value evaluates to False.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

The resulting time is adjusted for daylight-saving time, unless **ignore\_dst** is set to True.

### Places and time zones

The `ConvertToLocalTime` function retrieves information on places and time zones around the world from the Windows registry. This means that for the function to work, the name of the place you want to use must match the corresponding name in the Windows registry.

The exact name with which a place is registered in the Windows registry may also change according to the language settings of your Windows installation. This is because the names of certain cities and countries are spelled differently in different languages.

There is a full list of places and time zones in the windows registry in:

## 9 Script syntax and chart functions

`HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Time Zones`

Alternatively, you can find the list of time zones and places in Windows Control Panel. Open *Control Panel*, click on *Date and Time* settings and then *Change time zone*. You can see the full list of cities or countries associated with each time zone from the drop-down menu.

Valid places and time zones

| A-C                    | D-K                          | L-R                         | S-Z                 |
|------------------------|------------------------------|-----------------------------|---------------------|
| Abu Dhabi              | Darwin                       | La Paz                      | Samoa               |
| Adelaide               | Dhaka                        | Lima                        | Santiago            |
| Alaska                 | Eastern Time (US & Canada)   | Lisbon                      | Sapporo             |
| Amsterdam              | Edinburgh                    | Ljubljana                   | Sarajevo            |

| Copenhagen                 | -            | -                          | -                   |

### Examples and results

| Example                                                         | Result                                                                                                                                                                             |
|-----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>convertToLocalTime('2023-08-14 08:39:47', 'Paris')</code> | Returns '2023-08-14 10:39:47' and the corresponding internal timestamp representation.                                                                                             |
| <code>convertToLocalTime(UTC(), 'Stockholm')</code>             | Returns the time for Stockholm, adjusting for daylight saving time.                                                                                                                |
| <code>convertToLocalTime(UTC(), 'Stockholm', -1)</code>         | Returns the time for Stockholm, without daylight saving time adjustment.                                                                                                           |
| <code>convertToLocalTime(UTC(), 'GMT-05:00')</code>             | Returns the time for the North American east coast, for example, New York. No adjustment is made for daylight saving time because a GMT offset, rather than a place, is specified. |
| <code>convertToLocalTime(UTC(), 'New York', -1)</code>          | Returns the time for the North American east coast (New York), without daylight saving time adjustment.                                                                            |

| Example                                                     | Result                                                                                                  |
|-------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| <code>ConvertToLocalTime(UTC(), 'New York', True())</code>  | Returns the time for the North American east coast (New York), without daylight saving time adjustment. |
| <code>ConvertToLocalTime(UTC(), 'New York', 0)</code>       | Returns the time for the North American east coast (New York), adjusting for daylight saving time.      |
| <code>ConvertToLocalTime(UTC(), 'New York', False())</code> | Returns the time for the North American east coast (New York), adjusting for daylight saving time.      |

### Using GMT offsets in combination with DST

Following the implementation of International Components for Unicode (ICU) libraries in QlikView November 2018, the use of GMT (Greenwich Mean Time) offsets in combination with DST (Daylight Saving Time) requires additional latitudinal information.

GMT is a longitudinal (east-west) offset, whereas DST is a latitudinal (north-south) offset. For example, Helsinki (Finland) and Johannesburg (South Africa) share the same GMT+02:00 offset, but they do not share the same DST offset. This means that, further to the GMT offset, any DST offset requires information on the latitudinal position of the local time zone (geographical time zone input) in order to have full information about local DST conditions.

### day

This function returns an integer representing the day when the fraction of the **expression** is interpreted as a date according to the standard number interpretation.

#### Syntax:

```
day (expression)
```

**Return data type:** integer

#### Examples and results:

| Examples and results             |                                       |
|----------------------------------|---------------------------------------|
| Example                          | Result                                |
| <code>day( '1971-10-12' )</code> | returns 12                            |
| <code>day( '35648' )</code>      | returns 6, because 35648 = 1997-08-06 |

### dayend

This function returns a value corresponding to a timestamp of the final millisecond of the day contained in **time**. The default output format will be the **TimestampFormat** set in the script.

### Syntax:

```
DayEnd (time[, [period_no[, day_start]])
```

**Return data type:** dual

### Arguments:

DayEnd arguments

| Argument         | Description                                                                                                                                                                                                                                          |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>time</b>      | The timestamp to evaluate.                                                                                                                                                                                                                           |
| <b>period_no</b> | <b>period_no</b> is an integer, or expression that resolves to an integer, where the value 0 indicates the day that contains <b>time</b> . Negative values in <b>period_no</b> indicate preceding days and positive values indicate succeeding days. |
| <b>day_start</b> | To specify days not starting at midnight, indicate an offset as a fraction of a day in <b>day_start</b> . For example, 0.125 to denote 3 AM.                                                                                                         |

### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

#### Example 1:

```
dayend('25/01/2013 16:45:00')
```

Returns 25/01/2013 23:59:59.

#### Example 2:

```
dayend('25/01/2013 16:45:00', -1)
```

Returns '24/01/2013 23:59:59.

#### Example 3:

```
dayend('25/01/2013 16:45:00', 0, 0.5)
```

Returns 26/01/2013 11:59:59.

#### Example 4:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example finds the timestamp that marks the end of the day after each invoice date in the table.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
```

```
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];
```

```
InvoiceData:
LOAD *,
DayEnd(InvDate, 1) AS DEnd
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the dayend() function. You can display the full timestamp by specifying the formatting in the chart properties.

Example 4 results

| InvDate    | DEnd                |
|------------|---------------------|
| 28/03/2012 | 29/03/2012 23:59:59 |
| 10/12/2012 | 11/12/2012 23:59:59 |
| 5/2/2013   | 07/02/2013 23:59:59 |
| 31/3/2013  | 01/04/2013 23:59:59 |
| 19/5/2013  | 20/05/2013 23:59:59 |
| 15/9/2013  | 16/09/2013 23:59:59 |
| 11/12/2013 | 12/12/2013 23:59:59 |
| 2/3/2014   | 03/03/2014 23:59:59 |
| 14/5/2014  | 15/05/2014 23:59:59 |
| 13/6/2014  | 14/06/2014 23:59:59 |
| 7/7/2014   | 08/07/2014 23:59:59 |
| 4/8/2014   | 05/08/2014 23:59:59 |

### daylightsaving

Returns the current adjustment for daylight saving time, as defined in Windows.

#### Syntax:

```
DaylightSaving ()
```

**Return data type:** dual

### Example:

```
daylightsaving()
```

### dayname

This function returns a value showing the date with an underlying numeric value corresponding to a timestamp of the first millisecond of the day containing **time**.

### Syntax:

```
DayName (time[, period_no [, day_start]])
```

**Return data type:** dual

### Arguments:

DayName arguments

| Argument         | Description                                                                                                                                                                                                                                          |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>time</b>      | The timestamp to evaluate.                                                                                                                                                                                                                           |
| <b>period_no</b> | <b>period_no</b> is an integer, or expression that resolves to an integer, where the value 0 indicates the day that contains <b>time</b> . Negative values in <b>period_no</b> indicate preceding days and positive values indicate succeeding days. |
| <b>day_start</b> | To specify days not starting at midnight, indicate an offset as a fraction of a day in <b>day_start</b> . For example, 0.125 to denote 3 AM.                                                                                                         |

### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

#### Example 1:

```
dayname('25/01/2013 16:45:00')
```

Returns 25/01/2013.

#### Example 2:

```
dayname('25/01/2013 16:45:00', -1)
```

Returns 24/01/2013.

#### Example 3:

```
dayname('25/01/2013 16:45:00', 0, 0.5)
```

Returns 25/01/2013.

Displaying the full timestamp shows the underlying numeric value corresponds to '25/01/2013 12:00:00.000.

### Example 4:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

In this example, the day name is created from the timestamp that marks the beginning of the day after each invoice date in the table.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];
```

```
InvoiceData:
LOAD *,
DayName(InvDate, 1) AS DName
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the dayname() function. You can display the full timestamp by specifying the formatting in the chart properties.

Example 4 results

| InvDate    | DName               |
|------------|---------------------|
| 28/03/2012 | 29/03/2012 00:00:00 |
| 10/12/2012 | 11/12/2012 00:00:00 |
| 5/2/2013   | 07/02/2013 00:00:00 |
| 31/3/2013  | 01/04/2013 00:00:00 |
| 19/5/2013  | 20/05/2013 00:00:00 |
| 15/9/2013  | 16/09/2013 00:00:00 |

### daynumberofquarter

This function calculates the day number of the quarter in which a timestamp falls.

#### Syntax:

```
DayNumberOfQuarter(timestamp[, start_month])
```

**Return data type:** integer

The function always uses years based on 366 days.

#### Arguments:

DayNumberOfQuarter arguments

| Argument           | Description                                                                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>timestamp</b>   | The date to evaluate.                                                                                                                                                                                                                                    |
| <b>start_month</b> | By specifying a <b>start_month</b> between 2 and 12 (1, if omitted), the beginning of the year may be moved forward to the first day of any month. For example, if you want to work with a fiscal year starting March 1, specify <b>start_month</b> = 3. |

#### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

##### Example 1:

```
DayNumberOfQuarter('12/09/2014')
```

Returns 74, the day number of the current quarter.

##### Example 2:

```
DayNumberOfQuarter('12/09/2014', 3)
```

Returns 12, the day number of the current quarter.

In this case, the first quarter starts with March (because `start_month` is specified as 3). This means that the current quarter is the third quarter, which started on September 1.

### Example 3:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
ProjectTable:
LOAD recno() as InvID, * INLINE [
StartDate
28/03/2014
10/12/2014
5/2/2015
31/3/2015
19/5/2015
15/9/2015
] ;
NrDays:
Load *,
DayNumberOfQuarter(StartDate,4) As DayNrQtr
Resident ProjectTable;
Drop table ProjectTable;
```

The resulting table shows the returned values of DayNumberOfQuarter for each of the records in the table.

Example 3 results

| InvID | StartDate  | DayNrQtr |
|-------|------------|----------|
| 1     | 28/03/2014 | 88       |
| 2     | 10/12/2014 | 71       |
| 3     | 5/2/2015   | 36       |
| 4     | 31/3/2015  | 91       |
| 5     | 19/5/2015  | 49       |
| 6     | 15/9/2015  | 77       |

### daynumberofyear

This function calculates the day number of the year in which a timestamp falls. The calculation is made from the first millisecond of the first day of the year, but the first month can be offset.

#### Syntax:

```
DayNumberOfYear (timestamp[,start_month])
```

**Return data type:** integer

The function always uses years based on 366 days.

### Arguments:

#### DayNumberOfYear arguments

| Argument           | Description                                                                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>timestamp</b>   | The date to evaluate.                                                                                                                                                                                                                                    |
| <b>start_month</b> | By specifying a <b>start_month</b> between 2 and 12 (1, if omitted), the beginning of the year may be moved forward to the first day of any month. For example, if you want to work with a fiscal year starting March 1, specify <b>start_month</b> = 3. |

### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

#### Example 1:

```
DayNumberOfYear('12/09/2014')
```

Returns 256, the day number counted from the first of the year.

#### Example 2:

```
DayNumberOfYear('12/09/2014',3)
```

Returns 196, the number of the day, as counted from 1 March.

#### Example 3:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
ProjectTable:
LOAD recno() as InvID, * INLINE [
StartDate
28/03/2014
10/12/2014
5/2/2015
31/3/2015
19/5/2015
15/9/2015
] ;
NrDays:
Load *,
DayNumberOfYear(StartDate,4) As DayNrYear
Resident ProjectTable;
Drop table ProjectTable;
```

The resulting table shows the returned values of DayNumberOfYear for each of the records in the table.

Example 3 results

| InvID | StartDate  | DayNrYear |
|-------|------------|-----------|
| 1     | 28/03/2014 | 363       |
| 2     | 10/12/2014 | 254       |
| 3     | 5/2/2015   | 311       |
| 4     | 31/3/2015  | 366       |
| 5     | 19/5/2015  | 49        |
| 6     | 15/9/2015  | 168       |

### daystart

This function returns a value corresponding to a timestamp with the first millisecond of the day contained in the **time** argument. The default output format will be the **TimestampFormat** set in the script.

#### Syntax:

```
DayStart (time[, [period_no[, day_start]])
```

**Return data type:** dual

#### Arguments:

DayStart arguments

| Argument         | Description                                                                                                                                                                                                                                          |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>time</b>      | The timestamp to evaluate.                                                                                                                                                                                                                           |
| <b>period_no</b> | <b>period_no</b> is an integer, or expression that resolves to an integer, where the value 0 indicates the day that contains <b>time</b> . Negative values in <b>period_no</b> indicate preceding days and positive values indicate succeeding days. |
| <b>day_start</b> | To specify days not starting at midnight, indicate an offset as a fraction of a day in <b>day_start</b> . For example, 0.125 to denote 3 AM.                                                                                                         |

#### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

##### Example 1:

```
daystart('25/01/2013 16:45:00')
```

Returns 25/01/2013 00:00:00.

##### Example 2:

```
daystart('25/01/2013 16:45:00', -1)
```

Returns 24/01/2013 00:00:00.

### Example 3:

```
daystart('25/01/2013 16:45:00', 0, 0.5)
```

Returns 25/01/2013 12:00:00.

### Example 4:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example finds the timestamp that marks the beginning of the day after each invoice date in the table.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];
```

```
InvoiceData:
LOAD *,
DayStart(InvDate, 1) AS DStart
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the daystart() function. You can display the full timestamp by specifying the formatting in the chart properties.

Example 4 results

| InvDate    | DStart              |
|------------|---------------------|
| 28/03/2012 | 29/03/2012 00:00:00 |
| 10/12/2012 | 11/12/2012 00:00:00 |
| 5/2/2013   | 06/02/2013 00:00:00 |
| 31/3/2013  | 01/04/2013 00:00:00 |
| 19/5/2013  | 20/05/2013 00:00:00 |
| 15/9/2013  | 16/09/2013 00:00:00 |
| 11/12/2013 | 12/12/2013 00:00:00 |

|           |                     |
|-----------|---------------------|
| 2/3/2014  | 03/03/2014 00:00:00 |
| 14/5/2014 | 15/05/2014 00:00:00 |
| 13/6/2014 | 14/06/2014 00:00:00 |
| 7/7/2014  | 08/07/2014 00:00:00 |
| 4/8/2014  | 05/08/2014 00:00:00 |

### firstworkdate

The **firstworkdate** function returns the latest starting date to achieve **no\_of\_workdays** (Monday-Friday) ending no later than **end\_date** taking into account any optionally listed holidays. **end\_date** and **holiday** should be valid dates or timestamps.

#### Syntax:

```
firstworkdate(end_date, no_of_workdays [, holiday])
```

**Return data type:** integer

#### Arguments:

FirstWorkDate arguments

| Argument              | Description                                                                                                                                                                                                                                                                                                                                     |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>end_date</b>       | The timestamp of end date to evaluate.                                                                                                                                                                                                                                                                                                          |
| <b>no_of_workdays</b> | The number of working days to achieve.                                                                                                                                                                                                                                                                                                          |
| <b>holiday</b>        | <p>Holiday periods to exclude from working days. A holiday period is stated as a start date and an end date, separated by commas.</p> <p><b>Example:</b> '25/12/2013', '26/12/2013'</p> <p>You can exclude more than one holiday period, separated by commas.</p> <p><b>Example:</b> '25/12/2013', '26/12/2013', '31/12/2013', '01/01/2014'</p> |

#### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

##### Example 1:

```
firstworkdate ('29/12/2014', 9)
```

Returns '17/12/2014'.

### Example 2:

```
firstworkdate ('29/12/2014', 9, '25/12/2014', '26/12/2014')
```

Returns 15/12/2014 because a holiday period of two days is taken into account.

### Example 3:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
ProjectTable:
LOAD *, recno() as InvID INLINE [
EndDate
28/03/2015
10/12/2015
5/2/2016
31/3/2016
19/5/2016
15/9/2016
] ;
NrDays:
Load *,
FirstWorkDate(EndDate,120) As StartDate
Resident ProjectTable;
Drop table ProjectTable;
```

The resulting table shows the returned values of FirstWorkDate for each of the records in the table.

Example 3 results

| InvID | EndDate    | StartDate  |
|-------|------------|------------|
| 1     | 28/03/2015 | 13/10/2014 |
| 2     | 10/12/2015 | 26/06/2015 |
| 3     | 5/2/2016   | 24/08/2015 |
| 4     | 31/3/2016  | 16/10/2015 |
| 5     | 19/5/2016  | 04/12/2015 |
| 6     | 15/9/2016  | 01/04/2016 |

## GMT

This function returns the date and current Greenwich Mean Time, as derived from the system clock and Windows time settings.

### Syntax:

```
GMT ()
```

**Return data type:** dual

### hour

This function returns an integer representing the hour when the fraction of the **expression** is interpreted as a time according to the standard number interpretation.

#### Syntax:

```
hour (expression)
```

**Return data type:** integer

#### Examples and results:

Examples and results

| Example            | Result                                   |
|--------------------|------------------------------------------|
| hour( '09:14:36' ) | returns 9                                |
| hour( '0.5555' )   | returns 13 ( Because 0.5555 = 13:19:55 ) |

### inday

This function returns True if **timestamp** lies inside the day containing **base\_timestamp**.

#### Syntax:

```
InDay (timestamp, base_timestamp, period_no[, day_start])
```

**Return data type:** Boolean

#### Arguments:

InDay arguments

| Argument              | Description                                                                                                                                                                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>timestamp</b>      | The date and time that you want to compare with <b>base_timestamp</b> .                                                                                                                                                                                          |
| <b>base_timestamp</b> | Date and time that is used to evaluate the timestamp.                                                                                                                                                                                                            |
| <b>period_no</b>      | The day can be offset by <b>period_no</b> . <b>period_no</b> is an integer, where the value 0 indicates the day which contains <b>base_timestamp</b> . Negative values in <b>period_no</b> indicate preceding days and positive values indicate succeeding days. |
| <b>day_start</b>      | If you want to work with days not starting midnight, indicate an offset as a fraction of a day in <b>day_start</b> , For example, 0.125 to denote 3 AM.                                                                                                          |

#### Example 1:

```
inday ('12/01/2006 12:23:00', '12/01/2006 00:00:00', 0)
```

Returns True

### Example 2:

```
inDay ('12/01/2006 12:23:00', '13/01/2006 00:00:00', 0)
```

Returns False

### Example 3:

```
inDay ('12/01/2006 12:23:00', '12/01/2006 00:00:00', -1)
```

Returns False

### Example 4:

```
inDay ('11/01/2006 12:23:00', '12/01/2006 00:00:00', -1)
```

Returns True

### Example 5:

```
inDay ('12/01/2006 12:23:00', '12/01/2006 00:00:00', 0, 0.5)
```

Returns False

### Example 6:

```
inDay ('12/01/2006 11:23:00', '12/01/2006 00:00:00', 0, 0.5)
```

Returns True

### Example 7:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example checks if an invoice date falls at any time in the day starting with the `base_timestamp`.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
 InvTime
 28/03/2012
 10/12/2012
 5/2/2013
];

InvoiceData:
LOAD *,
 InDay(InvTime, '28/03/2012 00:00:00', 0) AS InDayEx
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the `inDay()` function.

Example 7 results

| InvTime    | InDayEx   |
|------------|-----------|
| 28/03/2012 | -1 (True) |
| 10/12/2012 | 0 (False) |
| 5/2/2013   | 0 (False) |

### indaytotime

This function returns True if **timestamp** lies inside the part of day containing **base\_timestamp** up until and including the exact millisecond of **base\_timestamp**.

#### Syntax:

```
InDayToTime (timestamp, base_timestamp, period_no[, day_start])
```

**Return data type:** Boolean

#### Arguments:

InDayToTime arguments

| Argument              | Description                                                                                                                                                                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>timestamp</b>      | The date and time that you want to compare with <b>base_timestamp</b> .                                                                                                                                                                                          |
| <b>base_timestamp</b> | Date and time that is used to evaluate the timestamp.                                                                                                                                                                                                            |
| <b>period_no</b>      | The day can be offset by <b>period_no</b> . <b>period_no</b> is an integer, where the value 0 indicates the day which contains <b>base_timestamp</b> . Negative values in <b>period_no</b> indicate preceding days and positive values indicate succeeding days. |
| <b>day_start</b>      | (optional) If you want to work with days not starting midnight, indicate an offset as a fraction of a day in <b>day_start</b> , For example, 0.125 to denote 3 AM.                                                                                               |

#### Example 1:

```
indaytotime ('12/01/2006 12:23:00', '12/01/2006 23:59:00', 0)
```

Returns True

#### Example 2:

```
indaytotime ('12/01/2006 12:23:00', '12/01/2006 00:00:00', 0)
```

Returns False

#### Example 3:

```
indaytotime ('11/01/2006 12:23:00', '12/01/2006 23:59:00', -1)
```

Returns True

### Example 4:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example checks if an invoice timestamp falls before 17:00:00 on the day starting with the base\_timestamp.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvTime
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];

InvoiceData:
LOAD *,
InDayToTime(InvTime, '28/03/2012 17:00:00', 0) AS InDayExTT
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the indaytotime() function.

Example 4 results

| InvTime    | InDayExTT |
|------------|-----------|
| 28/03/2012 | -1 (True) |
| 10/12/2012 | 0 (False) |
| 5/2/2013   | 0 (False) |
| 31/3/2013  | 0 (False) |
| 19/5/2013  | 0 (False) |
| 15/9/2013  | 0 (False) |
| 11/12/2013 | 0 (False) |
| 2/3/2014   | 0 (False) |
| 14/5/2014  | 0 (False) |
| 13/6/2014  | 0 (False) |

|          |           |
|----------|-----------|
| 7/7/2014 | 0 (False) |
| 4/8/2014 | 0 (False) |

### inlunarweek

This function returns true if **timestamp** lies inside the lunar week containing **base\_date**. Lunar weeks in QlikView are defined by counting 1 January as the first day of the week.

#### Syntax:

```
InLunarWeek (timestamp, base_date, period_no[, first_week_day])
```

**Return data type:** Boolean

#### Arguments:

InLunarWeek arguments

| Argument              | Description                                                                                                                                                                                                                                                                             |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>timestamp</b>      | The date that you want to compare with <b>base_date</b> .                                                                                                                                                                                                                               |
| <b>base_date</b>      | Date that is used to evaluate the lunar week.                                                                                                                                                                                                                                           |
| <b>period_no</b>      | The lunar week can be offset by <b>period_no</b> . <b>period_no</b> is an integer, where the value 0 indicates the lunar week which contains <b>base_date</b> . Negative values in <b>period_no</b> indicate preceding lunar weeks and positive values indicate succeeding lunar weeks. |
| <b>first_week_day</b> | An offset that may be greater than or less than zero. This changes the beginning of the year by the specified number of days and/or fractions of a day.                                                                                                                                 |

#### Example 1:

```
inlunarweek('12/01/2013', '14/01/2013', 0)
```

Returns True. Because the value of timestamp, 12/01/2013 falls in the week 08/01/2013 to 14/01/2013.

#### Example 2:

```
inlunarweek('12/01/2013', '07/01/2013', 0)
```

Returns False. Because the base\_date 07/01/2013 is in the lunar week defined as 01/01/2013 to 07/01/2013.

#### Example 3:

```
inlunarweek('12/01/2013', '14/01/2013', -1)
```

Returns False. Because specifying a value of period\_no as -1 shifts the week to the previous week, 01/01/2013 to 07/01/2013.

#### Example 4:

```
inlunarweek('07/01/2013', '14/01/2013', -1)
```

Returns True. In comparison with the previous example, the timestamp is in the week after taking into account the shift backwards.

### Example 5:

```
inlunarweek('11/01/2006', '08/01/2006', 0, 3)
```

Returns False. Because specifying a value for first\_week\_day as 3 means the start of the year is calculated from 04/01/2013, and so the value of base\_date falls in the first week, and the value of timestamp falls in the week 11/01/2013 to 17/01/2013.

### Example 6:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example checks if an invoice date falls in the week shifted from the value of base\_date by four weeks.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];

InvoiceData:
LOAD *,
InLunarweek(InvDate, '11/01/2013', 4) AS InLWeekPlus4
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the inlunarweek() function.

The function returns True for the value of InvDate 5/2/2013 because the value of base\_date, 11/01/2013, is shifted by four weeks, and so falls in the week 5/02/2013 to 11/02/2013.

Example 6 results

| InvDate    | InLWeekPlus4 |
|------------|--------------|
| 28/03/2012 | 0 (False)    |
| 10/12/2012 | 0 (False)    |

|            |           |
|------------|-----------|
| 5/2/2013   | -1 (True) |
| 31/3/2013  | 0 (False) |
| 19/5/2013  | 0 (False) |
| 15/9/2013  | 0 (False) |
| 11/12/2013 | 0 (False) |
| 2/3/2014   | 0 (False) |
| 14/5/2014  | 0 (False) |
| 13/6/2014  | 0 (False) |
| 7/7/2014   | 0 (False) |
| 4/8/2014   | 0 (False) |

### inlunarweektodate

This function returns true if **timestamp** lies inside the part of the lunar week up to and including the last millisecond of **base\_date**. Lunar weeks in QlikView are defined by counting 1 January as the first day of the week.

#### Syntax:

```
InLunarWeekToDate (timestamp, base_date, period_no [, first_week_day])
```

**Return data type:** Boolean

#### Arguments:

InLunarWeekToDate arguments

| Argument          | Description                                                                                                                                                                                                                                                                             |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>timestamp</b>  | The date that you want to compare with <b>base_date</b> .                                                                                                                                                                                                                               |
| <b>base_date</b>  | Date that is used to evaluate the lunar week.                                                                                                                                                                                                                                           |
| <b>peroid_no</b>  | The lunar week can be offset by <b>period_no</b> . <b>period_no</b> is an integer, where the value 0 indicates the lunar week which contains <b>base_date</b> . Negative values in <b>period_no</b> indicate preceding lunar weeks and positive values indicate succeeding lunar weeks. |
| <b>week_start</b> | An offset that may be greater than or less than zero. This changes the beginning of the year by the specified number of days and/or fractions of a day.                                                                                                                                 |

#### Example 1:

```
inlunarweektodate('12/01/2013', '13/01/2013', 0)
```

Returns True. Because the value of timestamp, 12/01/2013 falls in the part of the week 08/01/2013 to 13/01/2013.

### Example 2:

```
inLunarweekToDate('12/01/2013', '11/01/2013', 0)
```

Returns False. Because the value of timestamp is later than the value base\_date even though the two dates are in the same lunar week before 12/01/2012.

### Example 3:

```
inLunarweekToDate('12/01/2006', '05/01/2006', 1)
```

Returns True. Specifying a value of 1 for period\_no shifts the base\_date forward one week, so the value of timestamp falls in the part of the lunar week.

### Example 4:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example checks if an invoice date falls in the part of the week shifted from the value of base\_date by four weeks.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];

InvoiceData:
LOAD *,
InLunarweekToDate(InvDate, '07/01/2013', 4) AS InLWeek2DP1us4
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the inLunarweek() function.

The function returns True for the value of InvDate5/2/2013 because the value of base\_date, 11/01/2013, is shifted by four weeks, and so falls in the part of the week 5/02/2013 to 07/02/2013.

Example 4 results

| InvDate    | InLWeek2DPlus4 |
|------------|----------------|
| 28/03/2012 | 0 (False)      |
| 10/12/2012 | 0 (False)      |
| 5/2/2013   | -1 (True)      |
| 31/3/2013  | 0 (False)      |
| 19/5/2013  | 0 (False)      |
| 15/9/2013  | 0 (False)      |
| 11/12/2013 | 0 (False)      |
| 2/3/2014   | 0 (False)      |
| 14/5/2014  | 0 (False)      |
| 13/6/2014  | 0 (False)      |
| 7/7/2014   | 0 (False)      |
| 4/8/2014   | 0 (False)      |

### inmonth

This function returns True if **timestamp** lies inside the month containing **base\_date**.

#### Syntax:

```
InMonth (timestamp, base_date, period_no[, first_month_of_year])
```

**Return data type:** Boolean

#### Arguments:

InMonth arguments

| Argument                   | Description                                                                                                                                                                                                                                                         |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>timestamp</b>           | The date that you want to compare with <b>base_date</b> .                                                                                                                                                                                                           |
| <b>base_date</b>           | Date that is used to evaluate the month.                                                                                                                                                                                                                            |
| <b>period_no</b>           | The month can be offset by <b>period_no</b> . <b>period_no</b> is an integer, where the value 0 indicates the month which contains <b>base_date</b> . Negative values in <b>period_no</b> indicate preceding months and positive values indicate succeeding months. |
| <b>first_month_of_year</b> | The <b>first_month_of_year</b> parameter is disabled and reserved for future use.                                                                                                                                                                                   |

#### Example 1:

```
inmonth ('25/01/2013', '01/01/2013', 0)
```

Returns True

### Example 2:

```
inmonth('25/01/2013', '01/04/2013', 0)
```

Returns False

### Example 3:

```
inmonth ('25/01/2013', '01/01/2013', -1)
```

Returns False

### Example 4:

```
inmonth ('25/12/2012', '01/01/2013', -1)
```

Returns True

### Example 5:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example checks if an invoice date falls at any time in the fourth month after the month in `base_date`, by specifying `period_no` as 4.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];

InvoiceData:
LOAD *,
InMonth(InvDate, '31/01/2013', 4) AS InMthPlus4
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the `inmonth()` function.

Example 5 results

| InvDate | InMthPlus4 |
|---------|------------|
|---------|------------|

|            |           |
|------------|-----------|
| 28/03/2012 | 0 (False) |
| 10/12/2012 | 0 (False) |
| 5/2/2013   | 0 (False) |
| 31/3/2013  | 0 (False) |
| 19/5/2013  | -1 (True) |
| 15/9/2013  | 0 (False) |
| 11/12/2013 | 0 (False) |
| 2/3/2014   | 0 (False) |
| 14/5/2014  | 0 (False) |
| 13/6/2014  | 0 (False) |
| 7/7/2014   | 0 (False) |
| 4/8/2014   | 0 (False) |

### inmonths

This function finds if a timestamp falls within the same month, bi-month, quarter, four-month period, or half-year as a base date. It is also possible to find if the timestamp falls within a previous or following time period.

#### Syntax:

```
InMonths(n_months, timestamp, base_date, period_no [, first_month_of_year])
```

**Return data type:** Boolean

#### Arguments:

InMonths arguments

| Argument                   | Description                                                                                                                                                                                                                                                                               |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>n_months</b>            | The number of months that defines the period. An integer or expression that resolves to an integer that must be one of: 1 (equivalent to the inmonth() function), 2 (bi-month), 3 (equivalent to the inquarter() function), 4 (four-month period), or 6 (half year).                      |
| <b>timestamp</b>           | The date that you want to compare with <b>base_date</b> .                                                                                                                                                                                                                                 |
| <b>base_date</b>           | Date that is used to evaluate the period.                                                                                                                                                                                                                                                 |
| <b>period_no</b>           | The period can be offset by <b>period_no</b> , an integer, or expression resolving to an integer, where the value 0 indicates the period that contains <b>base_date</b> . Negative values in <b>period_no</b> indicate preceding periods and positive values indicate succeeding periods. |
| <b>first_month_of_year</b> | If you want to work with (fiscal) years not starting in January, indicate a value between 2 and 12 in <b>first_month_of_year</b> .                                                                                                                                                        |

### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

#### Example 1:

```
inmonths(4, '25/01/2013', '25/04/2013', 0)
```

Returns True. Because the value of timestamp, 25/01/2013, lies within the four-month period 01/01/2013 to 30/04/2013, in which the value of base\_date, 25/04/2013 lies.

#### Example 2:

```
inmonths(4, '25/05/2013', '25/04/2013', 0)
```

Returns False. Because 25/05/2013 is outside the same period as the previous example.

#### Example 3:

```
inmonths(4, '25/11/2012', '01/02/2013', -1)
```

Returns True. Because the value of period\_no, -1, shifts the search period back one period of four months (the value of n-months), which makes the search period 01/09/2012 to 31/12/2012.

#### Example 4:

```
inmonths(4, '25/05/2006', '01/03/2006', 0, 3)
```

Returns True. Because the value of first\_month\_of\_year is set to 3, which makes the search period 01/03/2006 to 30/07/2006 instead of 01/01/2006 to 30/04/2006.

#### Example 5:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example checks if the invoice date in the table falls in the bi-month period that includes the base\_date shifted forwards by one bi-month period (by specifying period\_no as 1).

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
```

```
7/7/2014
4/8/2014
];
```

```
InvoiceData:
LOAD *,
InMonths(2, InvDate, '11/02/2013', 1) AS InMthsPlus1
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the InMonths() function.

The search period is 01/03/2013 to 30/04/2013, because the value of base\_date is shifted forwards two months from the value in the function (11/02/2013).

Example 5 results

| InvDate    | InMthsPlus1 |
|------------|-------------|
| 28/03/2012 | 0 (False)   |
| 10/12/2012 | 0 (False)   |
| 5/2/2013   | 0 (False)   |
| 31/3/2013  | -1 (True)   |
| 19/5/2013  | 0 (False)   |
| 15/9/2013  | 0 (False)   |
| 11/12/2013 | 0 (False)   |
| 2/3/2014   | 0 (False)   |
| 14/5/2014  | 0 (False)   |
| 13/6/2014  | 0 (False)   |
| 7/7/2014   | 0 (False)   |
| 4/8/2014   | 0 (False)   |

### inmonthstodate

This function finds if a timestamp falls within the part of a period of the month, bi-month, quarter, four-month period, or half-year up to and including the last millisecond of **base\_date**. It is also possible to find if the timestamp falls within a previous or following time period.

#### Syntax:

```
InMonths (n_months, timestamp, base_date, period_no[, first_month_of_year])
```

**Return data type:** Boolean

### Arguments:

#### InMonthsToDate arguments

| Argument                   | Description                                                                                                                                                                                                                                                                                    |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>n_months</b>            | The number of months that defines the period. An integer or expression that resolves to an integer that must be one of: 1 (equivalent to the <code>inmonth()</code> function), 2 (bi-month), 3 (equivalent to the <code>inquarter()</code> function), 4 (four-month period), or 6 (half year). |
| <b>timestamp</b>           | The date that you want to compare with <b>base_date</b> .                                                                                                                                                                                                                                      |
| <b>base_date</b>           | Date that is used to evaluate the period.                                                                                                                                                                                                                                                      |
| <b>period_no</b>           | The period can be offset by <b>period_no</b> , an integer, or expression resolving to an integer, where the value 0 indicates the period that contains <b>base_date</b> . Negative values in <b>period_no</b> indicate preceding periods and positive values indicate succeeding periods.      |
| <b>first_month_of_year</b> | If you want to work with (fiscal) years not starting in January, indicate a value between 2 and 12 in <b>first_month_of_year</b> .                                                                                                                                                             |

### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

#### Example 1:

```
inmonthstodate(4, '25/01/2013', '25/04/2013', 0)
```

Returns True. Because the value of timestamp, 25/01/2013, lies within the four-month period 01/01/2013 up to the end of 25/04/2013, in which the value of base\_date, 25/04/2013 lies.

#### Example 2:

```
inmonthstodate(4, '26/04/2013', '25/04/2006', 0)
```

Returns False. Because 26/04/2013 is outside the same period as the previous example.

#### Example 3:

```
inmonthstodate(4, '25/09/2005', '01/02/2006', -1)
```

Returns True. Because the value of period\_no, -1, shifts the search period back one period of four months (the value of n-months), which makes the search period 01/09/2005 to 01/02/2006.

#### Example 4:

```
inmonthstodate(4, '25/04/2006', '01/06/2006', 0, 3)
```

Returns True. Because the value of first\_month\_of\_year is set to 3, which makes the search period 01/03/2006 to 01/06/2006 instead of 01/05/2006 to 01/06/2006.

### Example 5:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example checks if the invoice date in the table falls in the part of the bi-month period up to and including the base\_date shifted forwards by four bi-month periods (by specifying period\_no as 4).

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];

InvoiceData:
LOAD *,
InMonthsToDate(2, InvDate, '15/02/2013', 4) AS InMths2DPlus4
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the InMonths() function.

The search period is 01/09/2013 to 15/10/2013, because the value of base\_date is shifted forwards eight months from the value in the function (15/02/2013).

Example 5 results

| InvDate    | InMths2DPlus4 |
|------------|---------------|
| 28/03/2012 | 0 (False)     |
| 10/12/2012 | 0 (False)     |
| 5/2/2013   | 0 (False)     |
| 31/3/2013  | 0 (False)     |
| 19/5/2013  | 0 (False)     |
| 15/9/2013  | -1 (True)     |
| 11/12/2013 | 0 (False)     |
| 2/3/2014   | 0 (False)     |

|           |           |
|-----------|-----------|
| 14/5/2014 | 0 (False) |
| 13/6/2014 | 0 (False) |
| 7/7/2014  | 0 (False) |
| 4/8/2014  | 0 (False) |

### inmonthtodate

Returns True if **timestamp** lies inside the part of month containing **base\_date** up until and including the last millisecond of **base\_date**.

#### Syntax:

```
InMonthToDate (timestamp, base_date, period_no)
```

**Return data type:** Boolean

#### Arguments:

InMonthToDate arguments

| Argument         | Description                                                                                                                                                                                                                                                         |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>timestamp</b> | The date that you want to compare with <b>base_date</b> .                                                                                                                                                                                                           |
| <b>base_date</b> | Date that is used to evaluate the month.                                                                                                                                                                                                                            |
| <b>period_no</b> | The month can be offset by <b>period_no</b> . <b>period_no</b> is an integer, where the value 0 indicates the month which contains <b>base_date</b> . Negative values in <b>period_no</b> indicate preceding months and positive values indicate succeeding months. |

#### Example 1:

```
inmonthtodate ('25/01/2013', '25/01/2013', 0)
```

Returns True

#### Example 2:

```
inmonthtodate ('25/01/2013', '24/01/2013', 0)
```

Returns False

#### Example 3:

```
inmonthtodate ('25/01/2013', '28/02/2013', -1)
```

Returns True

#### Example 4:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

---

## 9 Script syntax and chart functions

---

By specifying `period_no` as 4, this example checks if an invoice date falls in the fourth month after the month in `base_date` but before the end of the day specified in `base_date`.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];

InvoiceData:
LOAD *,
InMonthToDate(InvDate, '31/01/2013', 4) AS InMthPlus42D
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the `inmonthtodate()` function.

Example 4 results

| InvDate    | InMthPlus42D |
|------------|--------------|
| 28/03/2012 | 0 (False)    |
| 10/12/2012 | 0 (False)    |
| 5/2/2013   | 0 (False)    |
| 31/3/2013  | 0 (False)    |
| 19/5/2013  | -1 (True)    |
| 15/9/2013  | 0 (False)    |
| 11/12/2013 | 0 (False)    |
| 2/3/2014   | 0 (False)    |
| 14/5/2014  | 0 (False)    |
| 13/6/2014  | 0 (False)    |
| 7/7/2014   | 0 (False)    |
| 4/8/2014   | 0 (False)    |

### inquarter

This function returns True if **timestamp** lies inside the quarter containing **base\_date**.

**Syntax:**

```
InQuarter (timestamp, base_date, period_no[, first_month_of_year])
```

**Return data type:** Boolean

**Arguments:**

InQuarter arguments

| Argument                   | Description                                                                                                                                                                                                                                                                 |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>timestamp</b>           | The date that you want to compare with <b>base_date</b> .                                                                                                                                                                                                                   |
| <b>base_date</b>           | Date that is used to evaluate the quarter.                                                                                                                                                                                                                                  |
| <b>period_no</b>           | The quarter can be offset by <b>period_no</b> . <b>period_no</b> is an integer, where the value 0 indicates the quarter which contains <b>base_date</b> . Negative values in <b>period_no</b> indicate preceding quarters and positive values indicate succeeding quarters. |
| <b>first_month_of_year</b> | If you want to work with (fiscal) years not starting in January, indicate a value between 2 and 12 in <b>first_month_of_year</b> .                                                                                                                                          |

**Example 1:**

```
inquarter ('25/01/2013', '01/01/2013', 0)
```

Returns True

**Example 2:**

```
inquarter ('25/01/2013', '01/04/2013', 0)
```

Returns False

**Example 3:**

```
inquarter ('25/01/2013', '01/01/2013', -1)
```

Returns False

**Example 4:**

```
inquarter ('25/12/2012', '01/01/2013', -1)
```

Returns True

**Example 5:**

```
inquarter ('25/01/2013', '01/03/2013', 0, 3)
```

Returns False

### Example 6:

```
inquarter ('25/03/2013', '01/03/2013', 0, 3)
```

Returns True

### Example 7:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example checks if an invoice date falls in the fourth quarter of the fiscal year specified by setting the value of `first_month_of_year` to 4, and having the `base_date` 31/01/2013.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];

InvoiceData:
LOAD *,
InQuarter(InvDate, '31/01/2013', 0, 4) AS Qtr4FinYr1213
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the `inquarter()` function.

Example 7 results

| InvDate    | Qtr4Fin1213 |
|------------|-------------|
| 28/03/2012 | 0 (False)   |
| 10/12/2012 | 0 (False)   |
| 5/2/2013   | -1 (True)   |
| 31/3/2013  | -1 (True)   |
| 19/5/2013  | 0 (False)   |
| 15/9/2013  | 0 (False)   |
| 11/12/2013 | 0 (False)   |

|           |           |
|-----------|-----------|
| 2/3/2014  | 0 (False) |
| 14/5/2014 | 0 (False) |
| 13/6/2014 | 0 (False) |
| 7/7/2014  | 0 (False) |
| 4/8/2014  | 0 (False) |

### inquartertodate

This function returns True if **timestamp** lies inside the part of the quarter containing **base\_date** up until and including the last millisecond of **base\_date**.

#### Syntax:

```
InQuarterToDate (timestamp, base_date, period_no [, first_month_of_year])
```

**Return data type:** Boolean

#### Arguments:

InQuarterToDate arguments

| Argument                   | Description                                                                                                                                                                                                                                                                 |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>timestamp</b>           | The date that you want to compare with <b>base_date</b> .                                                                                                                                                                                                                   |
| <b>base_date</b>           | Date that is used to evaluate the quarter.                                                                                                                                                                                                                                  |
| <b>period_no</b>           | The quarter can be offset by <b>period_no</b> . <b>period_no</b> is an integer, where the value 0 indicates the quarter which contains <b>base_date</b> . Negative values in <b>period_no</b> indicate preceding quarters and positive values indicate succeeding quarters. |
| <b>first_month_of_year</b> | If you want to work with (fiscal) years not starting in January, indicate a value between 2 and 12 in <b>first_month_of_year</b> .                                                                                                                                          |

#### Example 1:

```
inquartertodate ('25/01/2013', '25/01/2013', 0)
```

Returns True

#### Example 2:

```
inquartertodate ('25/01/2013', '24/01/2013', 0)
```

Returns False

#### Example 3:

```
inquartertodate ('25/01/2012', '01/02/2013', -1)
```

Returns False

### Example 4:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example checks if an invoice date falls in a fiscal year specified by setting the value of `first_month_of_year` to 4, and in the fourth quarter, before the end of 28/02/2013.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];

InvoiceData:
LOAD *,
InQuarterToDate(InvDate, '28/02/2013', 0, 4) AS Qtr42Date
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the `inquartertodate()` function.

Example 4 results

| InvDate    | Qtr42Date |
|------------|-----------|
| 28/03/2012 | 0 (False) |
| 10/12/2012 | 0 (False) |
| 5/2/2013   | -1 (True) |
| 31/3/2013  | 0 (False) |
| 19/5/2013  | 0 (False) |
| 15/9/2013  | 0 (False) |
| 11/12/2013 | 0 (False) |
| 2/3/2014   | 0 (False) |
| 14/5/2014  | 0 (False) |
| 13/6/2014  | 0 (False) |

## 9 Script syntax and chart functions

---

|          |           |
|----------|-----------|
| 7/7/2014 | 0 (False) |
| 4/8/2014 | 0 (False) |

### inweek

This function returns True if **timestamp** lies inside the week containing **base\_date**.

#### Syntax:

```
InWeek (timestamp, base_date, period_no[, first_week_day])
```

**Return data type:** Boolean

#### Arguments:

##### InWeek arguments

| Argument              | Description                                                                                                                                                                                                                                                        |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>timestamp</b>      | The date that you want to compare with <b>base_date</b> .                                                                                                                                                                                                          |
| <b>base_date</b>      | Date that is used to evaluate the week.                                                                                                                                                                                                                            |
| <b>period_no</b>      | The week can be offset by <b>period_no</b> . <b>period_no</b> is an integer, where the value 0 indicates the week which contains <b>base_date</b> . Negative values in <b>period_no</b> indicate preceding weeks and positive values indicate succeeding weeks.    |
| <b>first_week_day</b> | By default, the first day of the week is Monday, starting at midnight between Sunday and Monday. To indicate the week starting on another day, specify an offset in <b>first_week_day</b> . This may be given as a whole number of days and/or fractions of a day. |

#### Example 1:

```
inweek ('12/01/2006', '14/01/2006', 0)
```

Returns True

#### Example 2:

```
inweek ('12/01/2006', '20/01/2006', 0)
```

Returns False

#### Example 3:

```
inweek ('12/01/2006', '14/01/2006', -1)
```

Returns False

#### Example 4:

```
inweek ('07/01/2006', '14/01/2006', -1)
```

Returns True

### Example 5:

```
inweek ('12/01/2006', '09/01/2006', 0, 3)
```

Returns False

Because `first_week_day` is specified as 3 (Thursday), which makes 12/01/2006 the first day of the week following the week containing 09/01/2006.

### Example 6:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example checks if an invoice date falls at any time in the fourth week after the week in `base_date`, by specifying `period_no` as 4.

```
TempTable:
LOAD RecNo() as InVID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];

InvoiceData:
LOAD *,
Inweek(InvDate, '11/01/2013', 4) AS InweekPlus4
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the `inweek()` function.

The `InvDate5/2/2013` falls within the week that is four weeks after the `base_date`: 11/1/2013.

Example 6 results

| InvDate    | InWeekPlus4 |
|------------|-------------|
| 28/03/2012 | 0 (False)   |
| 10/12/2012 | 0 (False)   |
| 5/2/2013   | -1 (True)   |
| 31/3/2013  | 0 (False)   |

|            |           |
|------------|-----------|
| 19/5/2013  | 0 (False) |
| 15/9/2013  | 0 (False) |
| 11/12/2013 | 0 (False) |
| 2/3/2014   | 0 (False) |
| 14/5/2014  | 0 (False) |
| 13/6/2014  | 0 (False) |
| 7/7/2014   | 0 (False) |
| 4/8/2014   | 0 (False) |

### inweektodate

This function returns True if **timestamp** lies inside the part of week containing **base\_date** up until and including the last millisecond of **base\_date**.

#### Syntax:

```
InWeekToDate (timestamp, base_date, period_no [, first_week_day])
```

**Return data type:** Boolean

#### Arguments:

InWeekToDate arguments

| Argument              | Description                                                                                                                                                                                                                                                        |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>timestamp</b>      | The date that you want to compare with <b>base_date</b> .                                                                                                                                                                                                          |
| <b>base_date</b>      | Date that is used to evaluate the week.                                                                                                                                                                                                                            |
| <b>period_no</b>      | The week can be offset by <b>period_no</b> . <b>period_no</b> is an integer, where the value 0 indicates the week which contains <b>base_date</b> . Negative values in <b>period_no</b> indicate preceding weeks and positive values indicate succeeding weeks.    |
| <b>first_week_day</b> | By default, the first day of the week is Monday, starting at midnight between Sunday and Monday. To indicate the week starting on another day, specify an offset in <b>first_week_day</b> . This may be given as a whole number of days and/or fractions of a day. |

#### Example 1:

```
inweektodate ('12/01/2006', '12/01/2006', 0)
```

Returns True

#### Example 2:

```
inweektodate ('12/01/2006', '11/01/2006', 0)
```

Returns False

### Example 3:

```
inweektoday ('12/01/2006', '18/01/2006', -1)
```

Returns False

Because period\_no is specified as -1, the effective data that timestamp is measured against is 11/01/2006.

### Example 4:

```
inweektoday ('11/01/2006', '12/01/2006', 0, 3)
```

Returns False

Because first\_week\_day is specified as 3 (Thursday), which makes 12/01/2006 the first day of the week following the week containing 12/01/2006.

### Example 5:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example checks if an invoice date falls during the fourth week after the week in base\_date, by specifying period\_no as 4, but before the value of base\_date.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];

InvoiceData:
LOAD *,
InWeekToDate(InvDate, '11/01/2013', 4) AS InWeek2DPlus4
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the inweek() function.

Example 5 results

| InvDate    | InWeek2DPlus4 |
|------------|---------------|
| 28/03/2012 | 0 (False)     |

|            |           |
|------------|-----------|
| 10/12/2012 | 0 (False) |
| 5/2/2013   | -1 (True) |
| 31/3/2013  | 0 (False) |
| 19/5/2013  | 0 (False) |
| 15/9/2013  | 0 (False) |
| 11/12/2013 | 0 (False) |
| 2/3/2014   | 0 (False) |
| 14/5/2014  | 0 (False) |
| 13/6/2014  | 0 (False) |
| 7/7/2014   | 0 (False) |
| 4/8/2014   | 0 (False) |

### inyear

This function returns True if **timestamp** lies inside the year containing **base\_date**.

#### Syntax:

```
InYear (timestamp, base_date, period_no [, first_month_of_year])
```

**Return data type:** Boolean

#### Arguments:

##### InYear arguments

| Argument                   | Description                                                                                                                                                                                                                                                     |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>timestamp</b>           | The date that you want to compare with <b>base_date</b> .                                                                                                                                                                                                       |
| <b>base_date</b>           | Date that is used to evaluate the year.                                                                                                                                                                                                                         |
| <b>period_no</b>           | The year can be offset by <b>period_no</b> . <b>period_no</b> is an integer, where the value 0 indicates the year that contains <b>base_date</b> . Negative values in <b>period_no</b> indicate preceding years, and positive values indicate succeeding years. |
| <b>first_month_of_year</b> | If you want to work with (fiscal) years not starting in January, indicate a value between 2 and 12 in <b>first_month_of_year</b> .                                                                                                                              |

#### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

#### Example 1:

```
inyear ('25/01/2013', '01/01/2013', 0)
```

Returns True

**Example 2:**

```
inyear ('25/01/2012', '01/01/2013', 0)
```

Returns False

**Example 3:**

```
inyear ('25/01/2013', '01/01/2013', -1)
```

Returns False

**Example 4:**

```
inyear ('25/01/2012', '01/01/2013', -1)
```

Returns True

**Example 5:**

```
inyear ('25/01/2013', '01/01/2013', 0, 3)
```

Returns True

**Example 6:**

```
inyear ('25/03/2013', '01/07/2013', 0, 3)
```

Returns False. The values of `base_date` and `first_month_of_year` specify that timestamp must fall within 01/03/2012 and 28/02/2013

**Example 7:**

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example checks if an invoice date falls in the fiscal year specified by setting the value of `first_month_of_year` to 4, and having the `base_date` between 1/4/2012 and 31/03/2013.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
```

```
4/8/2014
];
```

Test if InvDate is in the financial year 1/04/2012 to 31/03/2013:

```
InvoiceData:
LOAD *,
InYear(InvDate, '31/01/2013', 0, 4) AS FinYr1213
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the inyear() function.

Example 7 results

| InvDate    | FinYr1213 |
|------------|-----------|
| 28/03/2012 | 0 (False) |
| 10/12/2012 | -1 (True) |
| 5/2/2013   | -1 (True) |
| 31/3/2013  | -1 (True) |
| 19/5/2013  | 0 (False) |
| 15/9/2013  | 0 (False) |
| 11/12/2013 | 0 (False) |
| 2/3/2014   | 0 (False) |
| 14/5/2014  | 0 (False) |
| 13/6/2014  | 0 (False) |
| 7/7/2014   | 0 (False) |
| 4/8/2014   | 0 (False) |

### inyeartodate

This function returns True if **timestamp** lies inside the part of year containing **base\_date** up until and including the last millisecond of **base\_date**.

#### Syntax:

```
InYearToDate (timestamp, base_date, period_no[, first_month_of_year])
```

**Return data type:** Boolean

#### Arguments:

InYearToDate arguments

| Argument         | Description                                               |
|------------------|-----------------------------------------------------------|
| <b>timestamp</b> | The date that you want to compare with <b>base_date</b> . |

| Argument                   | Description                                                                                                                                                                                                                                                     |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>base_date</b>           | Date that is used to evaluate the year.                                                                                                                                                                                                                         |
| <b>period_no</b>           | The year can be offset by <b>period_no</b> . <b>period_no</b> is an integer, where the value 0 indicates the year that contains <b>base_date</b> . Negative values in <b>period_no</b> indicate preceding years, and positive values indicate succeeding years. |
| <b>first_month_of_year</b> | If you want to work with (fiscal) years not starting in January, indicate a value between 2 and 12 in <b>first_month_of_year</b> .                                                                                                                              |

### Example 1:

```
inyeartodate ('2013/01/25', '2013/02/01', 0)
```

Returns True

### Example 2:

```
inyeartodate ('2012/01/25', '2013/01/01', 0)
```

Returns False

### Example 3:

```
inyeartodate ('2012/01/25', '2013/02/01', -1)
```

Returns True

### Example 4:

```
inyeartodate ('2012/11/25', '2013/01/31', 0, 4)
```

Returns True

The value of timestamp falls inside the fiscal year beginning in the fourth month and before the value of `base_date`.

### Example 5:

```
inyeartodate ('2013/3/31', '2013/01/31', 0, 4)
```

Returns False

Compared with the previous example, the value of timestamp is still inside the fiscal year, but it is after the value of `base_date`, so it falls outside the part of the year.

### Example 6:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example checks if an invoice date falls in a fiscal year specified by setting the value of `first_month_of_year` to 4, and in the part of the year before the end of 31/01/2013.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];
```

```
InvoiceData:
LOAD *,
InYearToDate(InvDate, '31/01/2013', 0, 4) AS FinYr2Date
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the `inyeartodate()` function.

Example 6 results

| InvDate    | FinYr2Date |
|------------|------------|
| 28/03/2012 | 0 (False)  |
| 10/12/2012 | -1 (True)  |
| 5/2/2013   | 0 (False)  |
| 31/3/2013  | 0 (False)  |
| 19/5/2013  | 0 (False)  |
| 15/9/2013  | 0 (False)  |
| 11/12/2013 | 0 (False)  |
| 2/3/2014   | 0 (False)  |
| 14/5/2014  | 0 (False)  |
| 13/6/2014  | 0 (False)  |
| 7/7/2014   | 0 (False)  |
| 4/8/2014   | 0 (False)  |

### lastworkdate

The **lastworkdate** function returns the earliest ending date to achieve **no\_of\_workdays** (Monday-Friday) if starting at **start\_date** taking into account any optionally listed **holiday**. **start\_date** and **holiday** should be valid dates or timestamps.

### Syntax:

```
lastworkdate (start_date, no_of_workdays {, holiday})
```

**Return data type:** dual

### Arguments:

Lastworkdate arguments

| Argument              | Description                                                                                                                                                                                                                                                                                                                                     |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>start_date</b>     | The start date to evaluate.                                                                                                                                                                                                                                                                                                                     |
| <b>no_of_workdays</b> | The number of working days to achieve.                                                                                                                                                                                                                                                                                                          |
| <b>holiday</b>        | <p>Holiday periods to exclude from working days. A holiday period is stated as a start date and an end date, separated by commas.</p> <p><b>Example:</b> '25/12/2013', '26/12/2013'</p> <p>You can exclude more than one holiday period, separated by commas.</p> <p><b>Example:</b> '25/12/2013', '26/12/2013', '31/12/2013', '01/01/2014'</p> |

### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

#### Example 1:

```
lastworkdate ('19/12/2014', 9)
```

Returns '31/12/2014'

#### Example 2:

```
lastworkdate ('19/12/2014', 9, '2014-12-25', '2014-12-26')
```

Returns '02/01/2015' as a holiday period of two days is taken into account.

#### Example 3:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
ProjectTable:
LOAD *, recno() as InVID INLINE [
StartDate
28/03/2014
10/12/2014
5/2/2015
```

```
31/3/2015
19/5/2015
15/9/2015
] ;
NrDays:
Load *,
LastWorkDate(StartDate,120) As EndDate
Resident ProjectTable;
Drop table ProjectTable;
```

The resulting table shows the returned values of LastWorkDate for each of the records in the table.

Example 3 results

| InvID | StartDate  | EndDate    |
|-------|------------|------------|
| 1     | 28/03/2014 | 11/09/2014 |
| 2     | 10/12/2014 | 26/05/2015 |
| 3     | 5/2/2015   | 27/07/2015 |
| 4     | 31/3/2015  | 14/09/2015 |
| 5     | 19/5/2015  | 02/11/2015 |
| 6     | 15/9/2015  | 29/02/2016 |

### localtime

This function returns a timestamp of the current time from the system clock for a specified time zone.

#### Syntax:

```
LocalTime ([timezone [, ignoreDST]])
```

**Return data type:** dual

### LocalTime arguments

| Argument  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| timezone  | <p>The <b>timezone</b> is specified as a string containing any of the geographical places listed under <b>Time Zone</b> in the <b>Windows Control Panel</b> for <b>Date and Time</b> or as a string in the form 'GMT+hh:mm'. A list of accepted places and time zones is also presented in the table below.</p> <p>If no time zone is specified, the local time is returned.</p> <div style="border: 1px solid gray; padding: 10px; margin-top: 10px;"> <p> <i>If you use a DST offset (that is, you specify an <b>ignoreDST</b> argument value evaluating to False), you must specify a place, rather than a GMT offset, in the <b>place</b> argument. This is because adjusting for Daylight Saving Time requires latitudinal information in addition to the longitudinal information provided by a GMT offset. For more information, see <a href="#">Using GMT offsets in combination with DST</a> (page 1312).</i></p> </div> |
| ignoreDST | <p>If this argument evaluates to True, DST (daylight saving time) is ignored. Valid argument values include -1 and True().</p> <p>If this argument evaluates to False, the timestamp is adjusted for daylight saving time. Valid argument values include 0 and False().</p> <p>If the <b>ignoreDST</b> argument value is invalid, the function evaluates the expression as if the <b>ignoreDST</b> value evaluates to True (daylight savings time is ignored). If the <b>ignoreDST</b> argument value is not specified, the function evaluates the expression as if the <b>ignoreDST</b> value evaluates to False (timestamp is adjusted for daylight savings time).</p>                                                                                                                                                                                                                                                                                                                                           |

### Valid places and time zones

| A-C                    | D-K                        | L-R       | S-Z          |

### Examples and results:

The examples below are based on the function being called on 2023-08-14 08:39:47 local time, with the local time zone of the server or desktop environment being GMT-05:00, and in a region which has implemented daylight saving time as of this listed date.

#### Scripting examples

| Example                                   | Result                                                                                                                                                                            |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>localtime ()</code>                 | Returns the local time 2023-08-14 08:39:47.                                                                                                                                       |
| <code>localtime ('London')</code>         | Returns the local time in London, 2023-08-14 13:39:47.                                                                                                                            |
| <code>localtime ('GMT+02:00')</code>      | Returns the local time in the timezone of GMT+02:00, 2023-08-14 14:39:47. No adjustment is made for daylight saving time because a GMT offset, rather than a place, is specified. |
| <code>localtime ('Paris',-1)</code>       | Returns the local time in Paris with daylight savings time ignored, 2023-08-14 13:39:47.                                                                                          |
| <code>localtime ('Paris',True())</code>   | Returns the local time in Paris with daylight savings time ignored, 2023-08-14 13:39:47.                                                                                          |
| <code>localtime ('Paris',0)</code>        | Returns the local time in Paris, taking daylight savings time into account, 2023-08-14 14:39:47.                                                                                  |
| <code>localtime ('Paris',False ())</code> | Returns the local time in Paris, taking daylight savings time into account, 2023-08-14 14:39:47.                                                                                  |

### Using GMT offsets in combination with DST

Following the implementation of International Components for Unicode (ICU) libraries in QlikView November 2018, the use of GMT (Greenwich Mean Time) offsets in combination with DST (Daylight Saving Time) requires additional latitudinal information.

GMT is a longitudinal (east-west) offset, whereas DST is a latitudinal (north-south) offset. For example, Helsinki (Finland) and Johannesburg (South Africa) share the same GMT+02:00 offset, but they do not share the same DST offset. This means that, further to the GMT offset, any DST offset requires information on the latitudinal position of the local time zone (geographical time zone input) in order to have full information about local DST conditions.

### lunarweekend

This function returns a value corresponding to a timestamp of the last millisecond of the lunar week containing **date**. Lunar weeks in QlikView are defined by counting 1 January as the first day of the week.

### Syntax:

```
LunarweekEnd (date[, period_no[, first_week_day]])
```

**Return data type:** dual

### Arguments:

LunarweekEnd arguments

| Argument              | Description                                                                                                                                                                                                                                                           |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>date</b>           | The date to evaluate.                                                                                                                                                                                                                                                 |
| <b>period_no</b>      | <b>period_no</b> is an integer or expression resolving to an integer, where the value 0 indicates the lunar week which contains <b>date</b> . Negative values in <b>period_no</b> indicate preceding lunar weeks and positive values indicate succeeding lunar weeks. |
| <b>first_week_day</b> | An offset that may be greater than or less than zero. This changes the beginning of the year by the specified number of days and/or fractions of a day.                                                                                                               |

### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

#### Example 1:

```
└lunarweekend('12/01/2013')
```

Returns 14/01/2013 23:59:59.

#### Example 2:

```
└lunarweekend('12/01/2013', -1)
```

Returns 7/01/2013 23:59:59.

#### Example 3:

```
└lunarweekend('12/01/2013', 0, 1)
```

Returns 15/01/2013 23:59:59.

#### Example 4:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example finds the final day of the lunar week of each invoice date in the table, where the date is shifted by one week by specifying `period_no` as 1.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
```

```
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];
```

```
InvoiceData:
LOAD *,
LunarWeekEnd(InvDate, 1) AS LwkEnd
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the `lunarweekend()` function. You can display the full timestamp by specifying the formatting in the chart properties.

Example 4 results

| InvDate    | LWkEnd     |
|------------|------------|
| 28/03/2012 | 07/04/2012 |
| 10/12/2012 | 22/12/2012 |
| 5/2/2013   | 18/02/2013 |
| 31/3/2013  | 08/04/2013 |
| 19/5/2013  | 27/05/2013 |
| 15/9/2013  | 23/09/2013 |
| 11/12/2013 | 23/12/2013 |
| 2/3/2014   | 11/03/2014 |
| 14/5/2014  | 27/05/2014 |
| 13/6/2014  | 24/06/2014 |
| 7/7/2014   | 15/07/2014 |
| 4/8/2014   | 12/08/2014 |

### lunarweekname

This function returns a display value showing the year and lunar week number corresponding to a timestamp of the first millisecond of the first day of the lunar week containing **date**. Lunar weeks in QlikView are defined by counting 1 January as the first day of the week.

#### Syntax:

```
LunarWeekName (date [, period_no[, first_week_day]])
```

**Return data type:** dual

**Arguments:**

LunarWeekName arguments

| Argument              | Description                                                                                                                                                                                                                                                           |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>date</b>           | The date to evaluate.                                                                                                                                                                                                                                                 |
| <b>period_no</b>      | <b>period_no</b> is an integer or expression resolving to an integer, where the value 0 indicates the lunar week which contains <b>date</b> . Negative values in <b>period_no</b> indicate preceding lunar weeks and positive values indicate succeeding lunar weeks. |
| <b>first_week_day</b> | An offset that may be greater than or less than zero. This changes the beginning of the year by the specified number of days and/or fractions of a day.                                                                                                               |

**Example 1:**

```
lunarweekname('12/01/2013')
```

Returns 2013/02.

**Example 2:**

```
lunarweekname('12/01/2013', -1)
```

Returns 2013/01.

**Example 3:**

```
lunarweekname('12/01/2013', 0, 1)
```

Returns 2013/02.

**Example 4:**

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

In this example, for each invoice date in the table, the lunar week name is created from the year in which the week lies and its associated lunar week number, shifted one week by specifying `period_no` as 1.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
 InvDate
 28/03/2012
 10/12/2012
 5/2/2013
 31/3/2013
 19/5/2013
 15/9/2013
 11/12/2013
 2/3/2014
 14/5/2014
```

```
13/6/2014
7/7/2014
4/8/2014
];
```

```
InvoiceData:
LOAD *,
LunarWeekName(InvDate, 1) AS LWkName
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the `lunarweekname()` function. You can display the full timestamp by specifying the formatting in the chart properties.

Example 4 results

| InvDate    | LWkName |
|------------|---------|
| 28/03/2012 | 2012/14 |
| 10/12/2012 | 2012/51 |
| 5/2/2013   | 2013/07 |
| 31/3/2013  | 2013/14 |
| 19/5/2013  | 2013/21 |
| 15/9/2013  | 2013/38 |
| 11/12/2013 | 2013/51 |
| 2/3/2014   | 2014/10 |
| 14/5/2014  | 2014/21 |
| 13/6/2014  | 2014/25 |
| 7/7/2014   | 2014/28 |
| 4/8/2014   | 2014/32 |

### lunarweekstart

This function returns a value corresponding to a timestamp of the first millisecond of the lunar week containing **date**. Lunar weeks in QlikView are defined by counting 1 January as the first day of the week.

#### Syntax:

```
LunarweekStart(date[, period_no[, first_week_day]])
```

**Return data type:** dual

### Arguments:

LunarweekStart arguments

| Argument              | Description                                                                                                                                                                                                                                                           |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>date</b>           | The date to evaluate.                                                                                                                                                                                                                                                 |
| <b>period_no</b>      | <b>period_no</b> is an integer or expression resolving to an integer, where the value 0 indicates the lunar week which contains <b>date</b> . Negative values in <b>period_no</b> indicate preceding lunar weeks and positive values indicate succeeding lunar weeks. |
| <b>first_week_day</b> | An offset that may be greater than or less than zero. This changes the beginning of the year by the specified number of days and/or fractions of a day.                                                                                                               |

### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

#### Example 1:

```
Lunarweekstart('12/01/2013')
```

Returns 08/01/2013.

#### Example 2:

```
Lunarweekstart('12/01/2013', -1)
```

Returns 01/01/2013.

#### Example 3:

```
Lunarweekstart('12/01/2013', 0, 1)
```

Returns 09/01/2013.

Because the offset specified by setting **first\_week\_day** to 1 means the beginning of the year is changed to 02/01/2013.

#### Example 4:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example finds the first day of the lunar week of each invoice date in the table, where the date is shifted by one week by specifying **period\_no** as 1.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
 InvDate
 28/03/2012
 10/12/2012
```

```
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];
```

```
InvoiceData:
LOAD *,
LunarWeekStart(InvDate, 1) AS LwkStart
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the `lunarweekstart()` function. You can display the full timestamp by specifying the formatting in the chart properties.

Example 4 results

| InvDate    | LWkStart   |
|------------|------------|
| 28/03/2012 | 01/04/2012 |
| 10/12/2012 | 16/12/2012 |
| 5/2/2013   | 12/02/2013 |
| 31/3/2013  | 02/04/2013 |
| 19/5/2013  | 21/05/2013 |
| 15/9/2013  | 17/09/2013 |
| 11/12/2013 | 17/12/2013 |
| 2/3/2014   | 05/03/2014 |
| 14/5/2014  | 21/05/2014 |
| 13/6/2014  | 18/06/2014 |
| 7/7/2014   | 09/07/2014 |
| 4/8/2014   | 06/08/2014 |

### makedate

This function returns a date calculated from the year **YYYY**, the month **MM** and the day **DD**.

#### Syntax:

```
MakeDate (YYYY [, MM [, DD]])
```

**Return data type:** dual

### Arguments:

MakeDate arguments

| Argument | Description                                                             |
|----------|-------------------------------------------------------------------------|
| YYYY     | The year as an integer.                                                 |
| MM       | The month as an integer. If no month is stated, 1 (January) is assumed. |
| DD       | The day as an integer.<br>If no day is stated, 1 (the 1st) is assumed.  |

### Examples and results:

Examples and results

| Example                          | Result             |
|----------------------------------|--------------------|
| <code>makedate(2012)</code>      | returns 2012-01-01 |
| <code>makedate(12)</code>        | returns 0012-01-01 |
| <code>makedate(2012,12)</code>   | returns 2012-12-01 |
| <code>makedate(2012,2,14)</code> | returns 2012-02-14 |

### maketime

This function returns a time calculated from the hour **hh**, the minute **mm**, and the second **ss**.

#### Syntax:

```
MakeTime(hh [, mm [, ss]])
```

**Return data type:** dual

### Arguments:

MakeTime arguments

| Argument | Description                                                         |
|----------|---------------------------------------------------------------------|
| hh       | The hour as an integer.                                             |
| mm       | The minute as an integer.<br>If no minute is stated, 00 is assumed. |
| ss       | The second as an integer.<br>If no second is stated, 00 is assumed. |

### Examples and results:

Examples and results

| Example                             | Result           |
|-------------------------------------|------------------|
| <code>maketime( 22 )</code>         | returns 22:00:00 |
| <code>maketime( 22, 17 )</code>     | returns 22:17:00 |
| <code>maketime( 22, 17, 52 )</code> | returns 22:17:52 |

### makeweekdate

This function returns a date calculated from the year **YYYY**, the week **WW** and the day-of-week **D**.

#### Syntax:

```
MakeWeekDate (YYYY [, WW [, D]])
```

Return data type: dual

#### Arguments:

MakeWeekDate arguments

| Argument | Description                                                                           |
|----------|---------------------------------------------------------------------------------------|
| YYYY     | The year as an integer.                                                               |
| WW       | The week as an integer.                                                               |
| D        | The day-of-week as an integer.<br>If no day-of-week is stated, 0 (Monday) is assumed. |

### Examples and results:

Examples and results

| Example                             | Result                                    |
|-------------------------------------|-------------------------------------------|
| <code>makeweekdate(2014,6,6)</code> | returns 2014-02-09                        |
| <code>makeweekdate(2014,6,1)</code> | returns 2014-02-04                        |
| <code>makeweekdate(2014,6)</code>   | returns 2014-02-03 (weekday 0 is assumed) |

### minute

This function returns an integer representing the minute when the fraction of the **expression** is interpreted as a time according to the standard number interpretation.

#### Syntax:

```
minute (expression)
```

**Return data type:** integer

**Examples and results:**

Examples and results

| Example                            | Result                                   |
|------------------------------------|------------------------------------------|
| <code>minute ( '09:14:36' )</code> | returns 14                               |
| <code>minute ( '0.5555' )</code>   | returns 19 ( Because 0.5555 = 13:19:55 ) |

### month

This function returns a dual value with a month name as defined in the environment variable **MonthNames** and an integer between 1-12. The month is calculated from the date interpretation of the expression, according to the standard number interpretation.

**Syntax:**

```
month(expression)
```

**Return data type:** dual

**Examples and results:**

Examples and results

| Example                            | Result                                  |
|------------------------------------|-----------------------------------------|
| <code>month( '2012-10-12' )</code> | returns Oct                             |
| <code>month( '35648' )</code>      | returns Aug, because 35648 = 1997-08-06 |

### monthend

This function returns a value corresponding to a timestamp of the last millisecond of the last day of the month containing **date**. The default output format will be the **DateFormat** set in the script.

**Syntax:**

```
MonthEnd(date[, period_no])
```

**Return data type:** dual

**Arguments:**

MonthEnd arguments

| Argument         | Description                                                                                                                                                                                                           |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>date</b>      | The date to evaluate.                                                                                                                                                                                                 |
| <b>period_no</b> | <b>period_no</b> is an integer, which, if 0 or omitted, indicates the month that contains <b>date</b> . Negative values in <b>period_no</b> indicate preceding months and positive values indicate succeeding months. |

### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

#### Example 1:

```
monthend('19/02/2012')
```

Returns 29/02/2012 23:59:59.

#### Example 2:

```
monthend('19/02/2001', -1)
```

Returns 31/01/2001 23:59:59.

#### Example 3:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example finds the last day in the month of each invoice date in the table, where the `base_date` is shifted by four months by specifying `period_no` as 4.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
 InvDate
 28/03/2012
 10/12/2012
 5/2/2013
 31/3/2013
 19/5/2013
 15/9/2013
 11/12/2013
 2/3/2014
 14/5/2014
 13/6/2014
 7/7/2014
 4/8/2014
];
```

```
InvoiceData:
LOAD *,
 MonthEnd(InvDate, 4) AS MthEnd
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the `monthend()` function. You can display the full timestamp by specifying the formatting in the chart properties.

Example 3 results

| InvDate    | MthEnd      |
|------------|-------------|
| 28/03/2012 | 31/07/2012  |
| 10/12/2012 | 30/04/2013  |
| 5/2/2013   | 30/06/2013  |
| 31/3/2013  | 31/07/2013  |
| 19/5/2013  | 30/09/2013  |
| 15/9/2013  | 31/01//2014 |
| 11/12/2013 | 30/04//2014 |
| 2/3/2014   | 31/07//2014 |
| 14/5/2014  | 30/09/2014  |
| 13/6/2014  | 31/10/2014  |
| 7/7/2014   | 30/11/2014  |
| 4/8/2014   | 31/12/2014  |

### monthname

This function returns a display value showing the month (formatted according to the **MonthNames** script variable) and year with an underlying numeric value corresponding to a timestamp of the first millisecond of the first day of the month.

#### Syntax:

```
MonthName (date[, period_no])
```

**Return data type:** dual

#### Arguments:

MonthName arguments

| Argument         | Description                                                                                                                                                                                                           |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>date</b>      | The date to evaluate.                                                                                                                                                                                                 |
| <b>period_no</b> | <b>period_no</b> is an integer, which, if 0 or omitted, indicates the month that contains <b>date</b> . Negative values in <b>period_no</b> indicate preceding months and positive values indicate succeeding months. |

#### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

### Example 1:

```
monthname('19/10/2013')
```

Returns Oct 2013.

Because in this and the other examples, the **SET Monthnames** statement is set to Jan;Feb;Mar, and so on.

### Example 2:

```
monthname('19/10/2013', -1)
```

Returns Sep 2013.

### Example 3:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

In this example, for each invoice date in the table, the month name is created from the month name shifted four months from base\_date, and from the year.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];
```

```
InvoiceData:
LOAD *,
MonthName(InvDate, 4) AS MthName
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the monthname() function.

Example 3 results

| InvDate    | MthName  |
|------------|----------|
| 28/03/2012 | Jul 2012 |

|            |          |
|------------|----------|
| 10/12/2012 | Apr 2013 |
| 5/2/2013   | Jun 2013 |
| 31/3/2013  | Jul 2013 |
| 19/5/2013  | Sep 2013 |
| 15/9/2013  | Jan 2014 |
| 11/12/2013 | Apr 2014 |
| 2/3/2014   | Jul 2014 |
| 14/5/2014  | Sep 2014 |
| 13/6/2014  | Oct 2014 |
| 7/7/2014   | Nov 2014 |
| 4/8/2014   | Dec 2014 |

### monthsend

This function returns a value corresponding to a timestamp of the last millisecond of the month, bi-month, quarter, four-month period, or half-year containing a base date. It is also possible to find the timestamp for a previous or following time period.

#### Syntax:

```
MonthsEnd(n_months, date[, period_no [, first_month_of_year]])
```

**Return data type:** dual

#### Arguments:

MonthsEnd arguments

| Argument                   | Description                                                                                                                                                                                                                                                                               |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>n_months</b>            | The number of months that defines the period. An integer or expression that resolves to an integer that must be one of: 1 (equivalent to the inmonth() function), 2 (bi-month), 3 (equivalent to the inquarter() function), 4 (four-month period), or 6 (half year).                      |
| <b>date</b>                | The date to evaluate.                                                                                                                                                                                                                                                                     |
| <b>period_no</b>           | The period can be offset by <b>period_no</b> , an integer, or expression resolving to an integer, where the value 0 indicates the period that contains <b>base_date</b> . Negative values in <b>period_no</b> indicate preceding periods and positive values indicate succeeding periods. |
| <b>first_month_of_year</b> | If you want to work with (fiscal) years not starting in January, indicate a value between 2 and 12 in <b>first_month_of_year</b> .                                                                                                                                                        |

### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

#### Example 1:

```
monthsend(4, '19/07/2013')
```

Returns 31/08/2013.

#### Example 2:

```
monthsend(4, '19/10/2013', -1)
```

Returns 31/08/2013.

#### Example 3:

```
monthsend(4, '19/10/2013', 0, 2)
```

Returns 31/01/2014.

Because the start of the year becomes month 2.

#### Example 4:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example finds the end of the final day of the bi-month period for each invoice date, shifted forwards by one bi-month period.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013

## 9 Script syntax and chart functions

---

The resulting table contains the original dates and a column with the return value of the MonthsEnd() function.

Example 4 results

| InvDate    | BiMthsEnd  |
|------------|------------|
| 28/03/2012 | 30/06/2012 |
| 10/12/2012 | 28/02/2013 |
| 5/2/2013   | 30/04/2013 |
| 31/3/2013  | 30/06/2013 |
| 19/5/2013  | 31/08/2013 |
| 15/9/2013  | 31/12/2013 |
| 11/12/2013 | 28/02/2014 |
| 2/3/2014   | 30/06/2014 |
| 14/5/2014  | 31/08/2014 |
| 13/6/2014  | 31/08/2014 |
| 7/7/2014   | 31/10/2014 |
| 4/8/2014   | 31/10/2014 |

### monthsname

This function returns a display value representing the range of the months of the period (formatted according to the **MonthNames** script variable) as well as the year. The underlying numeric value corresponds to a timestamp of the first millisecond of the month, bi-month, quarter, four-month period, or half-year containing a base date.

#### Syntax:

```
MonthsName(n_months, date[, period_no[, first_month_of_year]])
```

**Return data type:** dual

#### Arguments:

MonthsName arguments

| Argument        | Description                                                                                                                                                                                                                                                          |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>n_months</b> | The number of months that defines the period. An integer or expression that resolves to an integer that must be one of: 1 (equivalent to the inmonth() function), 2 (bi-month), 3 (equivalent to the inquarter() function), 4 (four-month period), or 6 (half year). |
| <b>date</b>     | The date to evaluate.                                                                                                                                                                                                                                                |

| Argument                   | Description                                                                                                                                                                                                                                                                               |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>period_no</b>           | The period can be offset by <b>period_no</b> , an integer, or expression resolving to an integer, where the value 0 indicates the period that contains <b>base_date</b> . Negative values in <b>period_no</b> indicate preceding periods and positive values indicate succeeding periods. |
| <b>first_month_of_year</b> | If you want to work with (fiscal) years not starting in January, indicate a value between 2 and 12 in <b>first_month_of_year</b> .                                                                                                                                                        |

### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

#### Example 1:

```
monthsname(4, '19/10/2013')
```

Returns Sep-Dec 2013.

Because in this and the other examples, the **SET Monthnames** statement is set to Jan;Feb;Mar, and so on.

#### Example 2:

```
monthsname(4, '19/10/2013', -1)
```

Returns May-Aug 2013.

#### Example 3:

```
monthsname(4, '19/10/2013', 0, 2)
```

Returns Oct-Jan 2014.

Because the year is specified to begin in month 2, therefore the four-month period ends on the first month of the following year.

#### Example 4:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

In this example, for each invoice date in the table, the months name is created from the range of months in the bi-month period, and from the year. The range is offset by 4x2 months by specifying **period\_no** as 4.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
```

```
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];
```

```
InvoiceData:
LOAD *,
MonthsName(2, InvDate, 4) AS MthsName
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the monthsname() function.

Example 4 results

| InvDate    | MthsName     |
|------------|--------------|
| 28/03/2012 | Nov-Dec 2012 |
| 10/12/2012 | Jul-Aug 2013 |
| 5/2/2013   | Sep-Oct 2013 |
| 31/3/2013  | Nov-Dec2013  |
| 19/5/2013  | Jan-Feb 2014 |
| 15/9/2013  | May-Jun 2014 |
| 11/12/2013 | Jul-Aug 2014 |
| 2/3/2014   | Nov-Dec 2014 |
| 14/5/2014  | Jan-Feb 2015 |
| 13/6/2014  | Jan-Feb 2015 |
| 7/7/2014   | Mar-Apr 2015 |
| 4/8/2014   | Mar-Apr 2015 |

### monthsstart

This function returns a value corresponding to the timestamp of the first millisecond of the month, bi-month, quarter, four-month period, or half-year containing a base date. It is also possible to find the timestamp for a previous or following time period.

#### Syntax:

```
MonthsStart (n_months, date[, period_no [, first_month_of_year]])
```

**Return data type:** dual

### Arguments:

#### MonthsStart arguments

| Argument                   | Description                                                                                                                                                                                                                                                                               |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>n_months</b>            | The number of months that defines the period. An integer or expression that resolves to an integer that must be one of: 1 (equivalent to the inmonth() function), 2 (bi-month), 3 (equivalent to the inquarter() function), 4 (four-month period), or 6 (half year).                      |
| <b>date</b>                | The date to evaluate.                                                                                                                                                                                                                                                                     |
| <b>period_no</b>           | The period can be offset by <b>period_no</b> , an integer, or expression resolving to an integer, where the value 0 indicates the period that contains <b>base_date</b> . Negative values in <b>period_no</b> indicate preceding periods and positive values indicate succeeding periods. |
| <b>first_month_of_year</b> | If you want to work with (fiscal) years not starting in January, indicate a value between 2 and 12 in <b>first_month_of_year</b> .                                                                                                                                                        |

### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

#### Example 1:

```
monthsstart(4, '19/10/2013')
```

Returns 1/09/2013.

#### Example 2:

```
monthsstart(4, '19/10/2013', -1)
```

Returns 01/05/2013.

#### Example 3:

```
monthsstart(4, '19/10/2013', 0, 2)
```

Returns 01/10/2013.

Because the start of the year becomes month 2.

#### Example 4:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example finds the first day of the bi-month period for each invoice date, shifted forwards by one bi-month period.

TempTable:

```
LOAD RecNo() as InvID, * Inline [
 InvDate
 28/03/2012
 10/12/2012
 5/2/2013
 31/3/2013
 19/5/2013
 15/9/2013
 11/12/2013
 2/3/2014
 14/5/2014
 13/6/2014
 7/7/2014
 4/8/2014
];
```

InvoiceData:

```
LOAD *,
 MonthsStart(2, InvDate, 1) AS BiMthsStart
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the MonthsStart() function.

Example 4 results

| InvDate    | BiMthsStart |
|------------|-------------|
| 28/03/2012 | 01/05/2012  |
| 10/12/2012 | 01/01/2013  |
| 5/2/2013   | 01/03/2013  |
| 31/3/2013  | 01/05/2013  |
| 19/5/2013  | 01/07/2013  |
| 15/9/2013  | 01/11/2013  |
| 11/12/2013 | 01/01/2014  |
| 2/3/2014   | 01/05/2014  |
| 14/5/2014  | 01/07/2014  |
| 13/6/2014  | 01/07/2014  |
| 7/7/2014   | 01/09/2014  |
| 4/8/2014   | 01/09/2014  |

### monthstart

This function returns a value corresponding to a timestamp of the first millisecond of the first day of the month containing **date**. The default output format will be the **DateFormat** set in the script.

#### Syntax:

```
MonthStart (date[, period_no])
```

**Return data type:** dual

**Arguments:**

MonthStart arguments

| Argument         | Description                                                                                                                                                                                                           |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>date</b>      | The date to evaluate.                                                                                                                                                                                                 |
| <b>period_no</b> | <b>period_no</b> is an integer, which, if 0 or omitted, indicates the month that contains <b>date</b> . Negative values in <b>period_no</b> indicate preceding months and positive values indicate succeeding months. |

**Examples and results:**

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

**Example 1:**

```
monthstart('19/10/2001')
```

Returns 01/10/2001.

**Example 2:**

```
monthstart('19/10/2001', -1)
```

Returns 01/09/2001.

**Example 3:**

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example finds the first day in the month of each invoice date in the table, where the `base_date` is shifted by four months by specifying `period_no` as 4.

```
TempTable:
LOAD RecNo() as InVID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
```

```
];
```

```
InvoiceData:
LOAD *,
MonthStart(InvDate, 4) AS MthStart
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the monthstart() function. You can display the full timestamp by specifying the formatting in the chart properties.

Example 3 results

| InvDate    | MthStart   |
|------------|------------|
| 28/03/2012 | 01/07/2012 |
| 10/12/2012 | 01/04/2013 |
| 5/2/2013   | 01/06/2013 |
| 31/3/2013  | 01/07/2013 |
| 19/5/2013  | 01/09/2013 |
| 15/9/2013  | 01/01/2014 |
| 11/12/2013 | 01/04/2014 |
| 2/3/2014   | 01/07/2014 |
| 14/5/2014  | 01/09/2014 |
| 13/6/2014  | 01/10/2014 |
| 7/7/2014   | 01/11/2014 |
| 4/8/2014   | 01/12/2014 |

### networkdays

The **networkdays** function returns the number of working days (Monday-Friday) between and including **start\_date** and **end\_date** taking into account any optionally listed **holiday**.

#### Syntax:

```
networkdays (start_date, end_date [, holiday])
```

**Return data type:** integer

#### Arguments:

Networkdays arguments

| Argument          | Description                 |
|-------------------|-----------------------------|
| <b>start_date</b> | The start date to evaluate. |
| <b>end_date</b>   | The end date to evaluate.   |

| Argument       | Description                                                                                                                                                                                                                                                                                                                                     |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>holiday</b> | <p>Holiday periods to exclude from working days. A holiday period is stated as a start date and an end date, separated by commas.</p> <p><b>Example:</b> '25/12/2013', '26/12/2013'</p> <p>You can specify more than one holiday period, separated by commas.</p> <p><b>Example:</b> '25/12/2013', '26/12/2013', '31/12/2013', '01/01/2014'</p> |

### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

#### Example 1:

```
networkdays ('19/12/2013', '07/01/2014')
```

Returns 14. This example does not take holidays into account.

#### Example 2:

```
networkdays ('19/12/2013', '07/01/2014', '25/12/2013', '26/12/2013')
```

Returns 12. This example takes the holiday 25/12/2013 to 26/12/2013 into account.

#### Example 3:

```
networkdays ('19/12/2013', '07/01/2014', '25/12/2013', '26/12/2013', '31/12/2013',
'01/01/2014')
```

Returns 10. This example takes two holiday periods into account.

#### Example 4:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
PayTable:
LOAD recno() as InvID, * INLINE [
InvRec|InvPaid
28/03/2012|28/04/2012
10/12/2012|01/01/2013
5/2/2013|5/3/2013
31/3/2013|01/5/2013
19/5/2013|12/6/2013
15/9/2013|6/10/2013
11/12/2013|12/01/2014
2/3/2014|2/4/2014
14/5/2014|14/6/2014

| 8     | 2/3/2014   | 2/4/2014   | 23       |
| 9     | 14/5/2014  | 14/6/2014  | 23       |
| 10    | 13/6/2014  | 14/7/2014  | 22       |
| 11    | 7/7/2014   | 14/8/2014  | 29       |
| 12    | 4/8/2014   | 4/9/2014   | 24       |

### now

This function returns a timestamp of the current time from the system clock. The default value is 1.

#### Syntax:

```
now([timer_mode])
```

**Return data type:** dual

### Arguments:

Now arguments

| Argument   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| timer_mode | <p>Can have the following values:</p> <ul style="list-style-type: none"> <li>• 0 (time at last finished data load)</li> <li>• 1 (time at function call)</li> <li>• 2 (time when the document was opened)</li> </ul> <div style="border: 1px solid gray; padding: 5px; margin-top: 10px;"> <p> If you use the function in a load script, <b>timer_mode=0</b> will result in the time of the last finished data load, while <b>timer_mode=1</b> will give the time of the function call in the current data load.</p> </div> |

### Examples and results:

Examples and results

| Example | Result                                                                                                                                                                                                                                       |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| now( 0) | Returns the time when the last data load completed.                                                                                                                                                                                          |
| now( 1) | <ul style="list-style-type: none"> <li>• When used in a chart expression, this returns the time of the function call.</li> <li>• When used in a load script, this returns the time of the function call in the current data load.</li> </ul> |
| now( 2) | Returns the time when the document was opened.                                                                                                                                                                                               |

### quarterend

This function returns a value corresponding to a timestamp of the last millisecond of the quarter containing **date**. The default output format will be the **DateFormat** set in the script.

#### Syntax:

```
QuarterEnd(date[, period_no[, first_month_of_year]])
```

**Return data type:** dual

### Arguments:

QuarterEnd arguments

| Argument | Description           |
|----------|-----------------------|
| date     | The date to evaluate. |

| Argument                   | Description                                                                                                                                                                                                            |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>period_no</b>           | <b>period_no</b> is an integer, where the value 0 indicates the quarter which contains <b>date</b> . Negative values in <b>period_no</b> indicate preceding quarters and positive values indicate succeeding quarters. |
| <b>first_month_of_year</b> | If you want to work with (fiscal) years not starting in January, indicate a value between 2 and 12 in <b>first_month_of_year</b> .                                                                                     |

### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

#### Example 1:

```
quarterend('29/10/2005')
```

Returns 31/12/2005 23:59:59.

#### Example 2:

```
quarterend('29/10/2005', -1)
```

Returns 30/09/2005 23:59:59.

#### Example 3:

```
quarterend('29/10/2005', 0, 3)
```

Returns 30/11/2005 23:59:59.

#### Example 4:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example finds the last day in the quarter of each invoice date in the table, where the first month in the year is specified as month 3.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
```

```
7/7/2014
4/8/2014
];
```

```
InvoiceData:
LOAD *,
QuarterEnd(InvDate, 0, 3) AS QtrEnd
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the quarterend() function. You can display the full timestamp by specifying the formatting in the chart properties.

Example 4 results

| InvDate    | QtrEnd     |
|------------|------------|
| 28/03/2012 | 31/05/2012 |
| 10/12/2012 | 28/02/2013 |
| 5/2/2013   | 28/02/2013 |
| 31/3/2013  | 31/05/2013 |
| 19/5/2013  | 31/05/2013 |
| 15/9/2013  | 30/11/2013 |
| 11/12/2013 | 28/02/2014 |
| 2/3/2014   | 31/05/2014 |
| 14/5/2014  | 31/05/2014 |
| 13/6/2014  | 31/08/2014 |
| 7/7/2014   | 31/08/2014 |
| 4/8/2014   | 31/08/2014 |

### quartername

This function returns a display value showing the months of the quarter (formatted according to the **MonthNames** script variable) and year with an underlying numeric value corresponding to a timestamp of the first millisecond of the first day of the quarter.

#### Syntax:

```
QuarterName (date[, period_no[, first_month_of_year]])
```

**Return data type:** dual

### Arguments:

#### QuarterName arguments

| Argument                   | Description                                                                                                                                                                                                            |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>date</b>                | The date to evaluate.                                                                                                                                                                                                  |
| <b>period_no</b>           | <b>period_no</b> is an integer, where the value 0 indicates the quarter which contains <b>date</b> . Negative values in <b>period_no</b> indicate preceding quarters and positive values indicate succeeding quarters. |
| <b>first_month_of_year</b> | If you want to work with (fiscal) years not starting in January, indicate a value between 2 and 12 in <b>first_month_of_year</b> .                                                                                     |

### Example 1:

```
quartername('29/10/2013')
```

Returns Oct-Dec 2013.

### Example 2:

```
quartername('29/10/2013', -1)
```

Returns Jul-Sep 2013.

### Example 3:

```
quartername('29/10/2013', 0, 3)
```

Returns Sep-Nov 2013.

### Example 4:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

In this example, for each invoice date in the table, the quarter name is created based on the quarter containing *InvID*. The first month in the year is specified as month 4.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
```

```
13/6/2014
7/7/2014
4/8/2014
];
```

```
InvoiceData:
LOAD *,
QuarterName(InvDate, 0, 4) AS QtrName
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the quartername() function.

Example 4 results

| InvDate    | QtrName      |
|------------|--------------|
| 28/03/2012 | Jan-Mar 2011 |
| 10/12/2012 | Oct-Dec 2012 |
| 5/2/2013   | Jan-Mar 2012 |
| 31/3/2013  | Jan-Mar 2012 |
| 19/5/2013  | Apr-Jun 2013 |
| 15/9/2013  | Jul-Sep 2013 |
| 11/12/2013 | Oct-Dec 2013 |
| 2/3/2014   | Jan-Mar 2013 |
| 14/5/2014  | Apr-Jun 2014 |
| 13/6/2014  | Apr-Jun 2014 |
| 7/7/2014   | Jul-Sep 2014 |
| 4/8/2014   | Jul-Sep 2014 |

### quarterstart

This function returns a value corresponding to a timestamp of the first millisecond of the quarter containing **date**. The default output format will be the **DateFormat** set in the script.

#### Syntax:

```
QuarterStart(date[, period_no[, first_month_of_yea]])
```

**Return data type:** dual

### Arguments:

#### QuarterStart arguments

| Argument                   | Description                                                                                                                                                                                                            |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>date</b>                | The date to evaluate.                                                                                                                                                                                                  |
| <b>period_no</b>           | <b>period_no</b> is an integer, where the value 0 indicates the quarter which contains <b>date</b> . Negative values in <b>period_no</b> indicate preceding quarters and positive values indicate succeeding quarters. |
| <b>first_month_of_year</b> | If you want to work with (fiscal) years not starting in January, indicate a value between 2 and 12 in <b>first_month_of_year</b> .                                                                                     |

### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

#### Example 1:

```
quarterstart('29/10/2005')
```

Returns 01/10/2005.

#### Example 2:

```
quarterstart('29/10/2005', -1)
```

Returns 01/07/2005.

#### Example 3:

```
quarterstart('29/10/2005', 0, 3)
```

Returns 01/09/2005.

#### Example 4:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example finds the first day in the quarter of each invoice date in the table, where the first month in the year is specified as month 3.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
```

```
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];
```

```
InvoiceData:
LOAD *,
QuarterStart(InvDate, 0, 3) AS QtrStart
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the quarterstart() function. You can display the full timestamp by specifying the formatting in the chart properties.

Example 4 results

| InvDate    | QtrStart   |
|------------|------------|
| 28/03/2012 | 01/03/2012 |
| 10/12/2012 | 01/12/2012 |
| 5/2/2013   | 01/12/2012 |
| 31/3/2013  | 01/03/2013 |
| 19/5/2013  | 01/03/2013 |
| 15/9/2013  | 01/09/2013 |
| 11/12/2013 | 01/12/2013 |
| 2/3/2014   | 01/03/2014 |
| 14/5/2014  | 01/03/2014 |
| 13/6/2014  | 01/06/2014 |
| 7/7/2014   | 01/06/2014 |
| 4/8/2014   | 01/06/2014 |

### second

This function returns an integer representing the second when the fraction of the **expression** is interpreted as a time according to the standard number interpretation.

#### Syntax:

```
second (expression)
```

**Return data type:** integer

### Examples and results:

#### Examples and results

| Example                           | Result                                   |
|-----------------------------------|------------------------------------------|
| <code>second( '09:14:36' )</code> | returns 36                               |
| <code>second( '0.5555' )</code>   | returns 55 ( Because 0.5555 = 13:19:55 ) |

### setdateyear

This function takes as input a **timestamp** and a **year** and updates the **timestamp** with the **year** specified in input.

#### Syntax:

```
setdateyear (timestamp, year)
```

**Return data type:** dual

#### Arguments:

#### SetDateYear arguments

| Argument         | Description                                                                                                       |
|------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>timestamp</b> | The date to evaluate as a timestamp or expression resolving to a timestamp, to convert, for example '2012-10-12'. |
| <b>year</b>      | A four-digit year.                                                                                                |

### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

#### Example 1:

```
setdateyear ('29/10/2005', 2013)
```

Returns '29/10/2013'

#### Example 2:

```
setdateyear ('29/10/2005 04:26:14', 2013)
```

Returns '29/10/2013 04:26:14'

To see the time part of the timestamp in a chart, you must set the number formatting to Date and choose a value for Formatting that displays time values.

### Example 3:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
SetYear:
Load *,
SetDateYear(testdates, 2013) as NewYear
Inline [
testdates
1/11/2012
10/12/2012
1/5/2013
2/1/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];
```

The resulting table contains the original dates and a column in which the year has be set to 2013.

Example 3 results

| testdates  | NewYear    |
|------------|------------|
| 1/11/2012  | 1/11/2013  |
| 10/12/2012 | 10/12/2013 |
| 2/1/2012   | 2/1/2013   |
| 1/5/2013   | 1/5/2013   |
| 19/5/2013  | 19/5/2013  |
| 15/9/2013  | 15/9/2013  |
| 11/12/2013 | 11/12/2013 |
| 2/3/2014   | 2/3/2013   |
| 14/5/2014  | 14/5/2013  |
| 13/6/2014  | 13/6/2013  |
| 7/7/2014   | 7/7/2013   |
| 4/8/2014   | 4/8/2013   |

### setdateyearmonth

This function takes as input a **timestamp**, a **month** and a **year** and updates the **timestamp** with the **year** and the **month** specified in input..

#### Syntax:

```
SetDateYearMonth (timestamp, year, month)
```

**Return data type:** dual

#### Arguments:

SetDateYearMonth arguments

| Argument         | Description                                                                                                       |
|------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>timestamp</b> | The date to evaluate as a timestamp or expression resolving to a timestamp, to convert, for example '2012-10-12'. |
| <b>year</b>      | A four-digit year.                                                                                                |
| <b>month</b>     | A one or two-digit month.                                                                                         |

#### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

##### Example 1:

```
setdateyearmonth ('29/10/2005', 2013, 3)
```

Returns '29/03/2013'

##### Example 2:

```
setdateyearmonth ('29/10/2005 04:26:14', 2013, 3)
```

Returns '29/03/2013 04:26:14'

To see the time part of the timestamp in a chart, you must set the number formatting to Date and choose a value for Formatting that displays time values.

##### Example 3:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
SetYearMonth:
Load *,
SetDateYearMonth(testdates, 2013,3) as NewYearMonth
Inline [
testdates
1/11/2012
```

```
10/12/2012
2/1/2013
19/5/2013
15/9/2013
11/12/2013
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];
```

The resulting table contains the original dates and a column in which the year has be set to 2013.

Example 3 results

| testdates  | NewYearMonth |
|------------|--------------|
| 1/11/2012  | 1/3/2013     |
| 10/12/2012 | 10/3/2013    |
| 2/1/2012   | 2/3/2013     |
| 19/5/2013  | 19/3/2013    |
| 15/9/2013  | 15/3/2013    |
| 11/12/2013 | 11/3/2013    |
| 14/5/2014  | 14/3/2013    |
| 13/6/2014  | 13/3/2013    |
| 7/7/2014   | 7/3/2013     |
| 4/8/2014   | 4/3/2013     |

### timezone

This function returns the name of the current time zone, as defined in Windows, not taking into account the daylight savings adjustment.

#### Syntax:

```
TimeZone ()
```

**Return data type:** string

### today

This function returns the current date from the system clock.

#### Syntax:

```
today ([timer_mode])
```

**Return data type:** dual

### Arguments:

#### Today arguments

| Argument   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| timer_mode | <p>Can have the following values:</p> <ul style="list-style-type: none"> <li>• 0 (day of last finished data load)</li> <li>• 1 (day of function call)</li> <li>• 2 (day when the document was opened)</li> </ul> <div style="border: 1px solid #ccc; padding: 5px; margin-top: 10px;"> <p> <i>If you use the function in a load script, <b>timer_mode=0</b> will result in the day of the last finished data load, while <b>timer_mode=1</b> will give the day of the current data load.</i></p> </div> |

### Examples and results:

#### Examples and results

| Example   | Result                                                                                                                                                                         |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Today( 0) | Returns the day of the last finished data load.                                                                                                                                |
| Today( 1) | <p>When used in a chart expression, this returns the day of the function call.</p> <p>When used in a load script, this returns the day when the current data load started.</p> |
| Today( 2) | Returns the day when the document was opened.                                                                                                                                  |

## UTC

Returns the date and current Coordinated Universal Time.

### Syntax:

```
UTC ()
```

**Return data type:** dual

## week

This function returns an integer representing the week number according to ISO 8601. The week number is calculated from the date interpretation of the expression, according to the standard number interpretation.

### Syntax:

```
week (timestamp [, first_week_day [, broken_weeks [, reference_day]])
```

**Return data type:** integer

### Arguments:

#### Week arguments

| Argument              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>timestamp</b>      | The date to evaluate as a timestamp or expression resolving to a timestamp, to convert, for example '2012-10-12'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>first_week_day</b> | <p>Integer that defines which day to use as the first day of the week. By default, QlikView functions use Monday as the first day of the week. The following values can be used:</p> <ul style="list-style-type: none"><li>• 0 (= Monday)</li><li>• 1 (= Tuesday)</li><li>• 2 (= Wednesday)</li><li>• 3 (= Thursday)</li><li>• 4 (= Friday)</li><li>• 5 (= Saturday)</li><li>• 6 (= Sunday)</li></ul>                                                                                                                                                                                                                                                                                                                        |
| <b>broken_weeks</b>   | <p>The setting defines if weeks are broken or not.</p> <p>By default QlikView functions use unbroken weeks. This means that:</p> <ul style="list-style-type: none"><li>• In some years, week 1 starts in December, and in other years, week 52 or 53 continues into January.</li><li>• Week 1 always has at least 4 days in January.</li></ul> <p>The alternative is to use broken weeks.</p> <ul style="list-style-type: none"><li>• Week 52 or 53 do not continue into January.</li><li>• Week 1 starts on January 1 and is, in most cases, not a full week.</li></ul> <p>The following values can be used:</p> <ul style="list-style-type: none"><li>• 0 (=use unbroken weeks)</li><li>• 1 (= use broken weeks)</li></ul> |

| Argument                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>reference_<br/>day</b> | <p>The setting defines which day in January to set as reference day to define week 1. By default, QlikView functions use 4 as the reference day. This means that week 1 must contain January 4, or put differently, that week 1 must always have at least 4 days in January.</p> <p>The following values can be used to set a different reference day:</p> <ul style="list-style-type: none"><li>• 1 (= January 1)</li><li>• 2 (= January 2)</li><li>• 3 (= January 3)</li><li>• 4 (= January 4)</li><li>• 5 (= January 5)</li><li>• 6 (= January 6)</li><li>• 7 (= January 7)</li></ul> |

### Example 1:

```
week ('2012-10-12')
```

returns 41

### Example 2:

```
week('35648')
```

returns 32, because 35648 = 1997-08-06

### Example 3:

```
week('2012-10-12', 0, 1)
```

returns 42

## weekday

This function returns a dual value with:

- A day name as defined in the environment variable **DayNames**.
- An integer between 0-6 corresponding to the nominal day of the week (0-6).

### Syntax:

```
weekday(date [,first_week_day=0])
```

**Return data type:** dual

### Arguments:

#### Weekday arguments

| Argument              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>date</b>           | The date to evaluate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>first_week_day</b> | <p>If you don't specify <b>first_week_day</b>, the value of variable <b>FirstWeekDay</b> will be used as the first day of the week.</p> <p>If you want to use another day as the first day of the week, set <b>first_week_day</b> to:</p> <ul style="list-style-type: none"><li>• 0 for Monday</li><li>• 1 for Tuesday</li><li>• 2 for Wednesday</li><li>• 3 for Thursday</li><li>• 4 for Friday</li><li>• 5 for Saturday</li><li>• 6 for Sunday</li></ul> <p>The integer returned by the function will now use the first day of the week that you set with <b>first_week_day</b> as base (0).</p> |

### Example 1:

```
weekday('1971-10-12')
```

returns 'Tue' and 1

### Example 2:

```
weekday('1971-10-12' , 6)
```

returns 'Tue' and 2.

In this example we use Sunday (6) as the first day of the week.

### Example 3:

```
weekday('1971-10-12')
```

returns 'Tue' and 2.

## weekend

This function returns a value corresponding to a timestamp of the last millisecond of the last day (Sunday) of the calendar week containing **date**. The default output format will be the **DateFormat** set in the script.

### Syntax:

```
WeekEnd(date [, period_no = 0 [, first_week_day=0]])
```

**Return data type:** dual

**Arguments:**

### WeekEnd arguments

| Argument              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>date</b>           | The date to evaluate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>period_no</b>      | <b>shift</b> is an integer, where the value 0 indicates the week which contains <b>date</b> . Negative values in shift indicate preceding weeks and positive values indicate succeeding weeks.                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>first_week_day</b> | <p>If you don't specify <b>first_week_day</b>, the value of variable <b>FirstWeekDay</b> will be used as the first day of the week.</p> <p>If you want to use another day as the first day of the week, set <b>first_week_day</b> to:</p> <ul style="list-style-type: none"><li>• 0 for Monday</li><li>• 1 for Tuesday</li><li>• 2 for Wednesday</li><li>• 3 for Thursday</li><li>• 4 for Friday</li><li>• 5 for Saturday</li><li>• 6 for Sunday</li></ul> <p>The integer returned by the function will now use the first day of the week that you set with <b>first_week_day</b> as base (0).</p> |

**Examples and results:**

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

**Example 1:**

```
weekend('10/01/2013')
```

Returns 12/01/2013 23:59:59.

**Example 2:**

```
weekend('10/01/2013', -1)
```

Returns 06/01/2013 23:59:59.

**Example 3:**

```
weekend('10/01/2013', 0, 1)
```

Returns 14/01/2013 23:59:59.

### Example 4:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example finds the final day in the week following the week of each invoice date in the table.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];
```

```
InvoiceData:
LOAD *,
weekEnd(InvDate, 1) AS WkEnd
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the weekend() function. You can display the full timestamp by specifying the formatting in the chart properties.

Example 4 results

| InvDate    | WkEnd      |
|------------|------------|
| 28/03/2012 | 08/04/2012 |
| 10/12/2012 | 23/12/2012 |
| 5/2/2013   | 17/02/2013 |
| 31/3/2013  | 07/04/2013 |
| 19/5/2013  | 26/05/2013 |
| 15/9/2013  | 22/09/2013 |
| 11/12/2013 | 22/12/2013 |
| 2/3/2014   | 09/03/2014 |
| 14/5/2014  | 25/05/2014 |
| 13/6/2014  | 22/06/2014 |
| 7/7/2014   | 20/07/2014 |
| 4/8/2014   | 17/08/2014 |

### weekname

This function returns a value showing the year and week number with an underlying numeric value corresponding to a timestamp of the first millisecond of the first day of the week containing **date**.

#### Syntax:

```
WeekName (date [, period_no = 0 [, first_week_day=0]])
```

**Return data type:** dual

#### Arguments:

WeekName arguments

| Argument              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>date</b>           | The date to evaluate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>period_no</b>      | <b>shift</b> is an integer, where the value 0 indicates the week which contains <b>date</b> . Negative values in shift indicate preceding weeks and positive values indicate succeeding weeks.                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>first_week_day</b> | <p>If you don't specify <b>first_week_day</b>, the value of variable <b>FirstWeekDay</b> will be used as the first day of the week.</p> <p>If you want to use another day as the first day of the week, set <b>first_week_day</b> to:</p> <ul style="list-style-type: none"><li>• 0 for Monday</li><li>• 1 for Tuesday</li><li>• 2 for Wednesday</li><li>• 3 for Thursday</li><li>• 4 for Friday</li><li>• 5 for Saturday</li><li>• 6 for Sunday</li></ul> <p>The integer returned by the function will now use the first day of the week that you set with <b>first_week_day</b> as base (0).</p> |

#### Example 1:

```
weekname('12/01/2013')
```

Returns 2013/02.

#### Example 2:

```
weekname('12/01/2013', -1)
```

Returns 2013/01.

#### Example 3:

```
weekname('12/01/2013', 0, 1)
```

Returns '2013/02.

### Example 4:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

In this example, for each invoice date in the table, the week name is created from the year in which the week lies and its associated week number, shifted one week by specifying period\_no as 1.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];
```

```
InvoiceData:
LOAD *,
weekName(InvDate, 1) AS WkName
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the weekname() function. You can display the full timestamp by specifying the formatting in the chart properties.

Example 4 results

| InvDate    | WkName  |
|------------|---------|
| 28/03/2012 | 2012/14 |
| 10/12/2012 | 2012/51 |
| 5/2/2013   | 2013/07 |
| 31/3/2013  | 2013/14 |
| 19/5/2013  | 2013/21 |
| 15/9/2013  | 2013/38 |
| 11/12/2013 | 2013/51 |
| 2/3/2014   | 2014/10 |
| 14/5/2014  | 2014/21 |

|           |         |
|-----------|---------|
| 13/6/2014 | 2014/25 |
| 7/7/2014  | 2014/29 |
| 4/8/2014  | 2014/33 |

### weekstart

This function returns a value corresponding to a timestamp of the first millisecond of the first day (Monday) of the calendar week containing **date**. The default output format is the **DateFormat** set in the script.

#### Syntax:

```
WeekStart(date [, period_no = 0 [, first_week_day=0]])
```

**Return data type:** dual

#### Arguments:

##### WeekStart arguments

| Argument              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>date</b>           | The date to evaluate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>period_no</b>      | <b>shift</b> is an integer, where the value 0 indicates the week which contains <b>date</b> . Negative values in shift indicate preceding weeks and positive values indicate succeeding weeks.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>first_week_day</b> | <p>If you don't specify <b>first_week_day</b>, the value of variable <b>FirstWeekDay</b> will be used as the first day of the week.</p> <p>If you want to use another day as the first day of the week, set <b>first_week_day</b> to:</p> <ul style="list-style-type: none"> <li>• 0 for Monday</li> <li>• 1 for Tuesday</li> <li>• 2 for Wednesday</li> <li>• 3 for Thursday</li> <li>• 4 for Friday</li> <li>• 5 for Saturday</li> <li>• 6 for Sunday</li> </ul> <p>The integer returned by the function will now use the first day of the week that you set with <b>first_week_day</b> as base (0).</p> |

#### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

##### Example 1:

```
weekstart('12/01/2013')
```

Returns 07/01/2013.

### Example 2:

```
weekstart('12/01/2013', -1)
```

Returns 31/11/2012.

### Example 3:

```
weekstart('12/01/2013', 0, 1)
```

Returns 08/01/2013.

### Example 4:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example finds the first day of the week following the week of each invoice date in the table.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];
```

```
InvoiceData:
LOAD *,
weekStart(InvDate, 1) AS wkStart
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the weekstart() function. You can display the full timestamp by specifying the formatting in the chart properties.

Example 4 results

| InvDate    | WkStart    |
|------------|------------|
| 28/03/2012 | 02/04/2012 |
| 10/12/2012 | 17/12/2012 |
| 5/2/2013   | 11/02/2013 |

## 9 Script syntax and chart functions

|            |            |
|------------|------------|
| 31/3/2013  | 01/04/2013 |
| 19/5/2013  | 20/05/2013 |
| 15/9/2013  | 16/09/2013 |
| 11/12/2013 | 16/12/2013 |
| 2/3/2014   | 03/03/2014 |
| 14/5/2014  | 19/05/2014 |
| 13/6/2014  | 16/06/2014 |
| 7/7/2014   | 14/07/2014 |
| 4/8/2014   | 11/08/2014 |

### weekyear

This function returns the year to which the week number belongs according to ISO 8601. The week number ranges between 1 and approximately 52.

#### Syntax:

**weekyear** (expression)

**Return data type:** integer

#### Examples and results:

Examples and results

| Example                  | Result                                                    |
|--------------------------|-----------------------------------------------------------|
| weekyear( '1996-12-30' ) | returns 1997, because week 1 of 1997 starts on 1996-12-30 |
| weekyear( '1997-01-02' ) | returns 1997                                              |
| weekyear( '1997-12-28' ) | returns 1997                                              |
| weekyear( '1997-12-30' ) | returns 1998, because week 1 of 1998 starts on 1997-12-29 |
| weekyear( '1999-01-02' ) | returns 1998, because week 53 of 1998 ends on 1999-01-03  |

#### Limitations:

Some years, week #1 starts in December, e.g. December 1997. Other years start with week #53 of previous year, e.g. January 1999. For those few days when the week number belongs to another year, the functions **year** and **weekyear** will return different values.

### year

This function returns an integer representing the year when the **expression** is interpreted as a date according to the standard number interpretation.

### Syntax:

```
year (expression)
```

**Return data type:** integer

### Examples and results:

Examples and results

| Example                           | Result                                   |
|-----------------------------------|------------------------------------------|
| <code>year( '2012-10-12' )</code> | returns 2012                             |
| <code>year( '35648' )</code>      | returns 1997, because 35648 = 1997-08-06 |

### yearend

This function returns a value corresponding to a timestamp of the last millisecond of the last day of the year containing **date**. The default output format will be the **DateFormat** set in the script.

### Syntax:

```
YearEnd(date[, period_no[, first_month_of_year = 1]])
```

**Return data type:** dual

### Arguments:

YearEnd arguments

| Argument                   | Description                                                                                                                                                                                                   |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>date</b>                | The date to evaluate.                                                                                                                                                                                         |
| <b>period_no</b>           | <b>period_no</b> is an integer, where the value 0 indicates the year which contains <b>date</b> . Negative values in <b>period_no</b> indicate preceding years and positive values indicate succeeding years. |
| <b>first_month_of_year</b> | If you want to work with (fiscal) years not starting in January, indicate a value between 2 and 12 in <b>first_month_of_year</b> .                                                                            |

### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

#### Example 1:

```
yearend ('19/10/2001')
```

Returns 31/12/2001 23:59:59.

### Example 2:

```
yearend ('19/10/2001', -1)
```

Returns 31/12/2000 23:59:59.

### Example 3:

```
yearend ('19/10/2001', 0, 4)
```

Returns 31/03/2002 23:59:59.

### Example 4:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example finds the final day in the year of each invoice date in the table, where the first month in the year is specified as month 4.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];
```

```
InvoiceData:
LOAD *,
YearEnd(InvDate, 0, 4) AS YrEnd
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the yearend() function. You can display the full timestamp by specifying the formatting in the chart properties.

Example 4 results

| InvDate    | YrEnd      |
|------------|------------|
| 28/03/2012 | 31/03/2011 |
| 10/12/2012 | 31/03/2012 |

## 9 Script syntax and chart functions

|            |            |
|------------|------------|
| 5/2/2013   | 31/03/2013 |
| 31/3/2013  | 31/03/2013 |
| 19/5/2013  | 31/03/2014 |
| 15/9/2013  | 31/03/2014 |
| 11/12/2013 | 31/03/2014 |
| 2/3/2014   | 31/03/2014 |
| 14/5/2014  | 31/03/2015 |
| 13/6/2014  | 31/03/2015 |
| 7/7/2014   | 31/03/2015 |
| 4/8/2014   | 31/03/2015 |

### yearname

This function returns a four-digit year as display value with an underlying numeric value corresponding to a timestamp of the first millisecond of the first day of the year containing **date**.

#### Syntax:

```
YearName (date[, period_no[, first_month_of_year]])
```

**Return data type:** dual

#### Arguments:

YearName arguments

| Argument                   | Description                                                                                                                                                                                                   |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>date</b>                | The date to evaluate.                                                                                                                                                                                         |
| <b>period_no</b>           | <b>period_no</b> is an integer, where the value 0 indicates the year which contains <b>date</b> . Negative values in <b>period_no</b> indicate preceding years and positive values indicate succeeding years. |
| <b>first_month_of_year</b> | If you want to work with (fiscal) years not starting in January, indicate a value between 2 and 12 in <b>first_month_of_year</b> . The display value will then be a string showing two years.                 |

#### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

#### Example 1:

```
yearname ('19/10/2001')
```

Returns 2001.

### Example 2:

```
yearname ('19/10/2001', -1)
```

Returns '2000.

### Example 3:

```
yearname ('19/10/2001', 0, 4)
```

Returns '2001-2002.

### Example 4:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example creates a four-plus-four digit name for the years in which each invoice date in the table is found. This is because the first month in the year is specified as month 4.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];
```

```
InvoiceData:
LOAD *,
YearName(InvDate, 0, 4) AS YrName
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the yearname() function.

Example 4 results

| InvDate    | YrName    |
|------------|-----------|
| 28/03/2012 | 2011-2012 |
| 10/12/2012 | 2012-2013 |

|            |           |
|------------|-----------|
| 5/2/2013   | 2012-2013 |
| 31/3/2013  | 2012-2013 |
| 19/5/2013  | 2013-2014 |
| 15/9/2013  | 2013-2014 |
| 11/12/2013 | 2013-2014 |
| 2/3/2014   | 2013-2014 |
| 14/5/2014  | 2014-2015 |
| 13/6/2014  | 2014-2015 |
| 7/7/2014   | 2014-2015 |
| 4/8/2014   | 2014-2015 |

### yearstart

This function returns a timestamp corresponding to the start of the first day of the year containing **date**. The default output format will be the **DateFormat** set in the script.

#### Syntax:

```
YearStart (date[, period_no[, first_month_of_year]])
```

**Return data type:** dual

#### Arguments:

YearStart arguments

| Argument                   | Description                                                                                                                                                                                                   |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>date</b>                | The date to evaluate.                                                                                                                                                                                         |
| <b>period_no</b>           | <b>period_no</b> is an integer, where the value 0 indicates the year which contains <b>date</b> . Negative values in <b>period_no</b> indicate preceding years and positive values indicate succeeding years. |
| <b>first_month_of_year</b> | If you want to work with (fiscal) years not starting in January, indicate a value between 2 and 12 in <b>first_month_of_year</b> .                                                                            |

#### Examples and results:

These examples use the date format DD/MM/YYYY. The date format is specified in the **SET DateFormat** statement at the top of your load script. Change the format in the examples to suit your requirements.

#### Example 1:

```
yearstart ('19/10/2001')
```

Returns 01/01/2001.

### Example 2:

```
yearstart ('19/10/2001', -1)
```

Returns 01/01/2000.

### Example 3:

```
yearstart ('19/10/2001', 0, 4)
```

Returns 01/04/2001.

### Example 4:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

This example finds the first day in the year of each invoice date in the table, where the first month in the year is specified as month 4.

```
TempTable:
LOAD RecNo() as InvID, * Inline [
InvDate
28/03/2012
10/12/2012
5/2/2013
31/3/2013
19/5/2013
15/9/2013
11/12/2013
2/3/2014
14/5/2014
13/6/2014
7/7/2014
4/8/2014
];
```

```
InvoiceData:
LOAD *,
YearStart(InvDate, 0, 4) AS YrStart
Resident TempTable;
Drop table TempTable;
```

The resulting table contains the original dates and a column with the return value of the yearstart() function. You can display the full timestamp by specifying the formatting in the chart properties.

Example 4 results

| InvDate    | YrStart    |
|------------|------------|
| 28/03/2012 | 01/04/2011 |
| 10/12/2012 | 01/04/2012 |

|            |            |
|------------|------------|
| 5/2/2013   | 01/04/2012 |
| 31/3/2013  | 01/04/2012 |
| 19/5/2013  | 01/04/2013 |
| 15/9/2013  | 01/04/2013 |
| 11/12/2013 | 01/04/2013 |
| 2/3/2014   | 01/04/2013 |
| 14/5/2014  | 01/04/2014 |
| 13/6/2014  | 01/04/2014 |
| 7/7/2014   | 01/04/2014 |
| 4/8/2014   | 01/04/2014 |

### yeartodate

This function finds if the input date falls within the year of the date the script was last loaded, and returns True if it does, False if it does not.

#### Syntax:

```
YearToDate(timestamp [, yearoffset [, firstmonth [, todaydate]]])
```

**Return data type:** Boolean

If none of the optional parameters are used, the year to date means any date within one calendar year from January 1 up to and including the date of the last script execution.

#### Arguments:

YearToDate arguments

| Argument   | Description                                                                                                                                                                                                                                                                                        |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| timestamp  | The date to evaluate as a timestamp or expression resolving to a timestamp, to convert, for example '2012-10-12'.                                                                                                                                                                                  |
| yearoffset | By specifying a <b>yearoffset</b> , <b>yeartodate</b> returns True for the same period in another year. A negative <b>yearoffset</b> indicates a previous year, a positive offset a future year. The most recent year-to-date is achieved by specifying yearoffset = -1. If omitted, 0 is assumed. |
| firstmonth | By specifying a <b>firstmonth</b> between 1 and 12 (1 if omitted) the beginning of the year may be moved forward to the first day of any month. For example, if you want to work with a fiscal year beginning on May 1, specify <b>firstmonth</b> = 5.                                             |
| todaydate  | By specifying a <b>todaydate</b> (timestamp of the last script execution if omitted) it is possible to move the day used as the upper boundary of the period.                                                                                                                                      |

### Examples and results:

The following examples assume last reload time = 2011-11-18

Examples and results

| Example                                                    | Result        |
|------------------------------------------------------------|---------------|
| <code>yeartodate( '2010-11-18')</code>                     | returns False |
| <code>yeartodate( '2011-02-01')</code>                     | returns True  |
| <code>yeartodate( '2011-11-18')</code>                     | returns True  |
| <code>yeartodate( '2011-11-19')</code>                     | returns False |
| <code>yeartodate( '2011-11-19', 0, 1, '2011-12-31')</code> | returns True  |
| <code>yeartodate( '2010-11-18', -1)</code>                 | returns True  |
| <code>yeartodate( '2011-11-18', -1)</code>                 | returns False |
| <code>yeartodate( '2011-04-30', 0, 5)</code>               | returns False |
| <code>yeartodate( '2011-05-01', 0, 5)</code>               | returns True  |

## Document functions

These functions can be used in charts and script.

### **ReportComment** (*report\_number*)

Returns the comment of the report with the specified number within the active document.

### **ReportName** (*report\_number*)

Returns the name of the report with the specified number within the active document.

### **ReportID** (*report\_number*)

Returns the id of the report with the specified number within the active document.

### **ReportNumber** (*report\_id\_or\_name*)

Returns the number of the report with the specified id or name within the active document.

### **NoOfReports** ()

Returns the number of reports in the active document.

## Exponential and logarithmic functions

This section describes functions related to exponential and logarithmic calculations. All functions can be used in both the load script and in chart expressions.

In the functions below, the parameters are expressions where **x** and **y** should be interpreted as real valued numbers.

### **exp**

The natural exponential function,  $e^x$ , using the natural logarithm **e** as base. The result is a positive number.

```
exp (x)
```

#### **Examples and results:**

exp(3) returns 20.085.

### **log**

The natural logarithm of **x**. The function is only defined if  $x > 0$ . The result is a number.

```
log (x)
```

#### **Examples and results:**

log(3) returns 1.0986

### **log10**

The common logarithm (base 10) of **x**. The function is only defined if  $x > 0$ . The result is a number.

```
log10 (x)
```

#### **Examples and results:**

log10(3) returns 0.4771

### **pow**

Returns **x** to the power of **y**. The result is a number.

```
pow (x , y)
```

#### **Examples and results:**

pow(3, 3) returns 27

### **sqr**

**x** squared (**x** to the power of 2). The result is a number.

```
sqr (x)
```

#### **Examples and results:**

sqr(3) returns 9

### **sqrt**

Square root of **x**. The function is only defined if  $x \geq 0$ . The result is a positive number.

```
sqrt (x)
```

### Examples and results:

`sqrt(3)` returns 1.732

## Field functions

These functions can only be used in chart expressions.

Field functions either return integers or strings identifying different aspects of field selections.

### Count functions

`GetSelectedCount`

**GetSelectedCount()** finds the number of selected (green) values in a field.

```
GetSelectedCount (field_name [, include_excluded])
```

`GetAlternativeCount`

**GetAlternativeCount()** is used to find the number of alternative (white cell with gray text) values in the identified field.

```
GetAlternativeCount (field_name)
```

`GetPossibleCount`

**GetPossibleCount()** is used to find the number of possible (white) values in the identified field. If the identified field includes selections, then the selected (green) fields are also counted.

```
GetPossibleCount (field_name)
```

`GetExcludedCount`

**GetExcludedCount()** finds the number of excluded distinct values in the identified field. Only excluded (gray cell with white text) values are counted. Alternative (white cell with gray text) and selected excluded (gray cell with green text) values are not counted.

```
GetExcludedCount (field_name)
```

`GetNotSelectedCount`

This chart function returns the number of not-selected (red cell with black text) values in the field named **fieldname**. The field must be in and-mode for this function to be relevant.

```
GetNotSelectedCount (fieldname [, includeexcluded=false])
```

### Field and selection functions

`GetCurrentField`

**GetCurrentField()** is used to find the currently active field in the specified group.

```
GetCurrentField (group_name)
```

GetCurrentSelections

**GetCurrentSelections()** returns the current selections in the document.

```
GetCurrentSelections ([record_sep [,tag_sep [,value_sep [,max_values]]]])
```

GetFieldSelections

**GetFieldSelections()** returns a **string** with the current selections in a field.

```
GetFieldSelections (field_name [, value_sep [, max_values]])
```

GetObjectField

**GetObjectField()** returns the name of the dimension. **Index** is an optional integer denoting the dimension that should be returned.

```
GetObjectField (page 1375) ([index])
```

GetObjectMeasure

**GetObjectMeasure()** returns the name of the measure. **Index** is an optional integer denoting the measure that should be returned.

```
GetObjectMeasure ([index])
```

### GetAlternativeCount

**GetAlternativeCount()** is used to find the number of alternative (white cell with gray text) values in the identified field.

**Syntax:**

```
GetAlternativeCount (field_name)
```

**Return data type:** integer

**Arguments:**

- `field_name`: The field containing the range of data to be measured.

### Color of selection states in List Boxes

All information on this page refers to the color of selection states in a List Box with specific settings:

- The QlikView document configured to a **Color Scheme** of **Classic Extended**. See: *Selection Appearance* (page 222)
- List Box configured with **Show Alternatives** turned on. See: *Show Alternatives* (page 264)

The following table outlines the color scheme for each selection state in a List Box with this configuration.

Color scheme for List box with given configuration

| State       | Cell color | Text color |
|-------------|------------|------------|
| Alternative | White      | Gray       |

| State             | Cell color | Text color |
|-------------------|------------|------------|
| Deselected        | Red        | Black      |
| Excluded          | Gray       | White      |
| Possible          | White      | Black      |
| Selected          | Green      | Black      |
| Selected excluded | Gray       | Green      |

### Examples

The following examples use the **First name** field loaded to a list box, and the following syntax:

```
getAlternativeCount ([First name])
```

- Given that **John** is selected in **First name**, the script returns **4** as there are 4 unique and excluded (gray) values in **First name**.
- Given that **John** and **Peter** are selected, the script returns **3** as there are 3 unique and excluded (gray) values in **First name**.
- Given that no values are selected in **First name**, the script returns **0** as there are no selections.

Data used in example:

```
Names:
LOAD * inline [
"First name"|"Last name"|"Initials"|"Has cellphone"
John|Anderson|JA|Yes
Sue|Brown|SB|Yes
Mark|Carr|MC |No
Peter|Devonshire|PD|No
Jane|Elliot|JE|Yes
Peter|Franc|PF|Yes] (delimiter is '|');
```

### GetCurrentField

**GetCurrentField()** is used to find the currently active field in the specified group.

#### Syntax:

```
GetCurrentField (group_name)
```

**Return data type:** string

#### Arguments:

- `group_name`: The name of the group to be evaluated.

### Examples

In the following, the field **MyGroup** includes the fields Sales and Price, and the following syntax:

```
GetCurrentField (MyGroup)
```

- Given that **Sales** is active, the script returns **saLes**, the active field.

### GetCurrentSelections

**GetCurrentSelections()** returns the current selections in the document.

If options are used you will need to specify `record_sep`. To specify a new line set `record_sep` to `chr(13)&chr(10)`.

If all but two, or all but one, values, are selected, the format 'NOT x,y' or 'NOT y' will be used respectively. If you select all values and the count of all values is greater than `max_values`, the text ALL will be returned.

#### Syntax:

```
GetCurrentSelections ([record_sep [,tag_sep [,value_sep [,max_values]]]])
```

**Return data type:** string

#### Arguments:

- `record_sep`: Separator to be put between field records. The default is <CR><LF> meaning a new line.
- `tag_sep`: Separator to be put between the field name tag and the field values. The default is ':'.
- `value_sep`: The separator to be put between field values. The default is ','.
- `max_values`: The maximum number of field values to be individually listed. When a larger number of values is selected, the format 'x of y values' will be used instead. The default is 6.

#### Examples

The following examples use two fields loaded to different list boxes, one for **First name** name and one for **Initials**.

##### Example 1: John is selected in First name

```
GetCurrentSelections ()
returns 'First name: John'.
```

##### Example 2: John and Peter are selected in First name.

```
GetCurrentSelections ()
returns 'First name: John, Peter'.
```

##### Example 3: John is selected in First name and JA is selected in Initials.

```
GetCurrentSelections ()
returns 'First name: John; Peter and Initials: JA'.
```

##### Example 4: John is selected in First name and JA is selected in Initials.

```
GetCurrentSelections (chr(13)&chr(10) , ' = ')
returns 'First name = John and Initials = JA'.
```

**Example 5: all names except Sue selected in First name and no selections in Initials.**

```
=GetCurrentSelections(chr(13)&chr(10), '=', ', ', 3)
returns 'First name=NOT Sue'.
```

Data used in example:

```
Names:
LOAD * inline [
"First name"|"Last name"|"Initials"|"Has cellphone"
John|Anderson|JA|Yes
Sue|Brown|SB|Yes
Mark|Carr|MC |No
Peter|Devonshire|PD|No
Jane|Elliot|JE|Yes
Peter|Franc|PF|Yes] (delimiter is '|');
```

### GetExcludedCount

**GetExcludedCount()** finds the number of excluded distinct values in the identified field. Only excluded (gray cell with white text) values are counted. Alternative (white cell with gray text) and selected excluded (gray cell with green text) values are not counted.

**Syntax:**

```
GetExcludedCount (field_name)
```

**Return data type:** string

**Arguments:**

- `field_name`: The field containing the range of data to be measured.

### Color of selection states in List Boxes

All information on this page refers to the color of selection states in a List Box with specific settings:

- The QlikView document configured to a **Color Scheme** of **Classic Extended**. See: *Selection Appearance (page 222)*
- List Box configured with **Show Alternatives** turned on. See: *Show Alternatives (page 264)*

The following table outlines the color scheme for each selection state in a List Box with this configuration.

Color scheme for List box with given configuration

| State       | Cell color | Text color |
|-------------|------------|------------|
| Alternative | White      | Gray       |
| Deselected  | Red        | Black      |
| Excluded    | Gray       | White      |
| Possible    | White      | Black      |

| State             | Cell color | Text color |
|-------------------|------------|------------|
| Selected          | Green      | Black      |
| Selected excluded | Gray       | Green      |

### Examples

The following example uses three fields loaded to different listboxes: one for **First name**, one for **Last name**, and one for **Initials**.

#### Example 1: no values selected in First name

```
GetExcludedCount (Initials)
Returns 0. There are no selections.
```

#### Example 2: John selected in First name

```
GetExcludedCount (Initials)
Returns 5. There are 5 excluded values in Initials with gray color. The JA value will be white as it is associated with the selection John in First name.
```

#### Example 3: John and Peter selected in First name

```
GetExcludedCount (Initials)
Returns 3. John is associated with 1 value and Peter is associated with 2 values, in Initials.
```

#### Example 4: John and Peter selected in First name, Franc selected in Last name

```
GetExcludedCount ([First name])
Returns 3. There are 3 excluded values in First name with gray color. GetExcludedCount() only counts excluded values. Alternative and selected excluded values are not included in the count.
```

#### Example 5: John and Peter selected in First name, Franc and Anderson selected in Last name

```
GetExcludedCount (Initials)
Returns 4. There are 4 excluded values in Initials with gray color. The other two values (JA and PF) will be white or light yellow as they are associated with the selections John and Peter in First name.
```

#### Example 6: John and Peter selected in First name, Franc and Anderson selected in Last name

```
GetExcludedCount ([Last name])
Returns 3. There are 3 excluded values in Last name: Brown, Carr, and Elliot. The value Devonshire is an alternative value so it is not included in the count.
```

Data used in example:

```
Names:
LOAD * inline [
"First name"|"Last name"|Initials|"Has cellphone"
John|Anderson|JA|Yes
Sue|Brown|SB|Yes
Mark|Carr|MC |No
```

```
Peter|Devonshire|PD|No
Jane|Elliot|JE|Yes
Peter|Franc|PF|Yes] (delimiter is '|');
```

### GetFieldSelections

**GetFieldSelections()** returns a **string** with the current selections in a field.

If all but two, or all but one of the values are selected, the format 'NOT x,y' or 'NOT y' will be used respectively. If you select all values and the count of all values is greater than `max_values`, the text ALL will be returned.

#### Syntax:

```
GetFieldSelections (field_name [, value_sep [, max_values [, state_name]])
```

**Return data type:** string

Return string formats

| Format          | Description                                                                                                                                                                                                                       |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'a, b, c'       | If the number of selected values is <code>max_values</code> or less, the string returned is a list of the selected values.<br><br>The values are separated with <code>value_sep</code> as delimiter.                              |
| 'NOT a, b, c'   | If the number of non-selected values is <code>max_values</code> or less, the string returned is a list of the non-selected values with NOT as a prefix.<br><br>The values are separated with <code>value_sep</code> as delimiter. |
| 'x of y'        | x = the number of selected values<br><br>y = the total number of values<br><br>This is returned when $\text{max\_values} < x < (y - \text{max\_values})$ .                                                                        |
| 'ALL'           | Returned if all values are selected.                                                                                                                                                                                              |
| '.'             | Returned if no value is selected.                                                                                                                                                                                                 |
| <search string> | If you have selected using search, the search string is returned.                                                                                                                                                                 |

#### Arguments:

- `field_name`: The field containing the range of data to be measured.
- `value_sep`: The separator to be put between field values. The default is '|'.
- `max_values`: The maximum number of field values to be individually listed. When a larger number of values is selected, the format 'x of y values' will be used instead. The default is 6.
- `state_name`: The name of an alternate state that has been chosen for the specific visualization. If the **state\_name** argument is used, only the selections associated with the specified state name are taken into account. For more information, see *Alternate States (page 876)*.

### Examples

The following example uses the **First name** field loaded to a list box.

#### Example 1: John selected in First name

```
GetFieldSelections ([First name])
returns 'John'
```

#### Example 2: John and Peter selected in First name

```
GetFieldSelections ([First name])
returns 'John,Peter'
```

#### Example 3: John and Peter selected in First name

```
GetFieldSelections ([First name],'; ')
returns 'John; Peter'
```

#### Example 4: John, Sue, Mark selected in First name

```
GetFieldSelections ([First name],';',2)
returns 'NOT Jane;Peter', because the value 2 is stated as the value of the max_values argument.
Otherwise, the result would have been John; Sue; Mark.
```

Data used in example:

```
Names:
LOAD * inline [
"First name"|"Last name"|"Initials"|"Has cellphone"
John|Anderson|JA|Yes
Sue|Brown|SB|Yes
Mark|Carr|MC |No
Peter|Devonshire|PD|No
Jane|Elliot|JE|Yes
Peter|Franc|PF|Yes] (delimiter is '|');
```

### GetNotSelectedCount

This chart function returns the number of not-selected (red cell with black text) values in the field named **fieldname**. The field must be in and-mode for this function to be relevant.

#### Syntax:

```
GetNotSelectedCount (field_name [, include_excluded])
(Inherited) GetNotSelectedCount (FieldName [, IncludeExcluded])
```

#### Arguments:

- **field\_name**: The field containing the range of data to be measured.
- **include\_excluded**: If **IncludeExcluded** is **True()**, the count will include selected values, which are currently excluded by selections in other fields. If **False** or omitted, these values will not be included.

### Example:

```
GetNotSelectedCount (Year)
GetNotSelectedCount (Year,True())
```

### Color of selection states in List Boxes

All information on this page refers to the color of selection states in a List Box with specific settings:

- The QlikView document configured to a **Color Scheme** of **Classic Extended**. See: *Selection Appearance (page 222)*
- List Box configured with **Show Alternatives** turned on. See: *Show Alternatives (page 264)*

The following table outlines the color scheme for each selection state in a List Box with this configuration.

Color scheme for List box with given configuration

| State             | Cell color | Text color |
|-------------------|------------|------------|
| Alternative       | White      | Gray       |
| Deselected        | Red        | Black      |
| Excluded          | Gray       | White      |
| Possible          | White      | Black      |
| Selected          | Green      | Black      |
| Selected excluded | Gray       | Green      |

### GetObjectField

**GetObjectField()** returns the name of the dimension. **Index** is an optional integer denoting the dimension that should be returned.

*You cannot use this function in a chart in the following locations: title, subtitle, footer, reference line expression and min/max expression.*

### Syntax:

```
GetObjectField ([index])
```

### Example:

```
GetObjectField(1)
```

Example: Chart expression

*QlikView table showing examples of the GetObjectField function in a chart expression.*

Example GetObjectField usage

| transaction_date | customer_id | transaction_quantity | =GetObjectField () | =GetObjectField (0) | =GetObjectField (1) |
|------------------|-------------|----------------------|--------------------|---------------------|---------------------|
| 2018/08/30       | 049681      | 13                   | transaction_date   | transaction_date    | customer_id         |
| 2018/08/30       | 203521      | 6                    | transaction_date   | transaction_date    | customer_id         |
| 2018/08/30       | 203521      | 21                   | transaction_date   | transaction_date    | customer_id         |

In this example, transaction\_quantity is a measure and would therefore not return a result from the **GetObjectField** function. Use the **GetObjectMeasure** function instead.

### GetObjectMeasure

**GetObjectMeasure()** returns the name of the measure. **Index** is an optional integer denoting the measure that should be returned.

*You cannot use this function in a chart in the following locations: title, subtitle, footer, reference line expression and min/max expression.*

#### Syntax:

```
GetObjectMeasure ([index])
```

#### Example:

```
GetObjectMeasure(1)
```

Example: Chart expression

*QlikView table showing examples of the GetObjectMeasure function in a chart expression.*

Example GetObjectMeasure usage

| transaction_quantity | transaction_amount | =GetObjectMeasure () | =GetObjectMeasure (0) | =GetObjectMeasure (1) |
|----------------------|--------------------|----------------------|-----------------------|-----------------------|
| 13                   | 484.21             | transaction_quantity | transaction_quantity  | transaction_amount    |
| 6                    | 556.31             | transaction_quantity | transaction_quantity  | transaction_amount    |
| 21                   | 177.42             | transaction_quantity | transaction_quantity  | transaction_amount    |

If you want to return a dimension, use the **GetObjectField** function instead.

### GetPossibleCount

**GetPossibleCount()** is used to find the number of possible (white) values in the identified field. If the identified field includes selections, then the selected (green) fields are also counted.

For fields with selections, **GetPossibleCount()** returns the number of selected (green) fields.

**Return data type:** integer

### Syntax:

```
GetPossibleCount (field_name)
```

### Arguments:

- `field_name`: The field containing the range of data to be measured.

### Color of selection states in List Boxes

All information on this page refers to the color of selection states in a List Box with specific settings:

- The QlikView document configured to a **Color Scheme** of **Classic Extended**. See: *Selection Appearance (page 222)*
- List Box configured with **Show Alternatives** turned on. See: *Show Alternatives (page 264)*

The following table outlines the color scheme for each selection state in a List Box with this configuration.

Color scheme for List box with given configuration

| State             | Cell color | Text color |
|-------------------|------------|------------|
| Alternative       | White      | Gray       |
| Deselected        | Red        | Black      |
| Excluded          | Gray       | White      |
| Possible          | White      | Black      |
| Selected          | Green      | Black      |
| Selected excluded | Gray       | Green      |

### Examples

The following examples use two fields loaded to different list boxes, one for **First name** name and one for **Initials**.

#### Example 1: John selected in First name

```
GetPossibleCount ([Initials])
```

returns 1 as there is 1 value in Initials associated with the selection, **John**, in **First name**.

#### Example 2: John selected in First name

```
GetPossibleCount ([First name])
```

returns 1 as there is 1 selection, **John**, in **First name**.

#### Example 3: Peter selected in First name

```
GetPossibleCount ([Initials])
```

returns 2 as Peter is associated with 2 values in **Initials**.

### Example 4: no values selected in First name

```
GetPossibleCount ([First name])
```

returns 5 as there are no selections and there are 5 unique values in **First name**.

### Example 5: no values selected in First name

```
GetPossibleCount ([Initials])
```

returns 6 as there are no selections and there are 6 unique values in **Initials**.

Data used in example:

Names:

```
LOAD * inline [
"First name"|"Last name"|Initials|"Has cellphone"
John|Anderson|JA|Yes
Sue|Brown|SB|Yes
Mark|Carr|MC |No
Peter|Devonshire|PD|No
Jane|Elliot|JE|Yes
Peter|Franc|PF|Yes] (delimiter is '|');
```

## GetSelectedCount

**GetSelectedCount()** finds the number of selected (green) values in a field.

**Syntax:**

```
GetSelectedCount (field_name [, include_excluded])
```

**Return data type:** integer

**Arguments:**

- `field_name`: The field containing the range of data to be measured.
- `include_excluded`: If set to **True()**, the count will include selected values, which are currently excluded by selections in other fields. If False or omitted, these values will not be included.
- `state_name`: The name of an alternate state. If specified, the counted value for the field in the alternate state is returned. If no alternate state is provided, the default state is used.

## Color of selection states in List Boxes

All information on this page refers to the color of selection states in a List Box with specific settings:

- The QlikView document configured to a **Color Scheme** of **Classic Extended**. See: *Selection Appearance (page 222)*
- List Box configured with **Show Alternatives** turned on. See: *Show Alternatives (page 264)*

The following table outlines the color scheme for each selection state in a List Box with this configuration.

Color scheme for List box with given configuration

| State             | Cell color | Text color |
|-------------------|------------|------------|
| Alternative       | White      | Gray       |
| Deselected        | Red        | Black      |
| Excluded          | Gray       | White      |
| Possible          | White      | Black      |
| Selected          | Green      | Black      |
| Selected excluded | Gray       | Green      |

### Examples

The following example uses three fields loaded to different list boxes, one for **First name** name, one for **Initials** and one for **Has cellphone**.

#### Example 1: John selected in First name

```
GetSelectedCount ([First name])
returns 1 as one value is selected in First name.
```

#### Example 2: John selected in First name

```
GetSelectedCount ([Initials])
returns 0 as no values are selected in Initials.
```

#### Example 3: no selections in First name, all values selected in Initials, and Yes selected in Has cellphone

```
GetSelectedCount ([Initials], True())
returns 6. Although selections with InitialsMC and PD have Has cellphone set to No, the result is still 6, because the argument include_excluded is set to True().
```

Data used in example:

```
Names:
LOAD * inline [
"First name"|"Last name"|Initials|"Has cellphone"
John|Anderson|JA|Yes
Sue|Brown|SB|Yes
Mark|Carr|MC |No
Peter|Devonshire|PD|No
Jane|Elliot|JE|Yes
Peter|Franc|PF|Yes] (delimiter is '|');
```

### File functions

The file functions (only available in script expressions) return information about the table file which is currently being read. These functions will return NULL for all data sources except table files (exception: **ConnectString()**).

### File functions overview

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

#### Attribute

This script function returns the value of the meta tags of different media files as text. The following file formats are supported: MP3, WMA, WMV, PNG and JPG. If the file **filename** does not exist, is not a supported file format or does not contain a meta tag named **attributename**, NULL will be returned.

```
Attribute (filename, attributename)
```

#### ConnectionString

The **ConnectionString()** function returns the name of the active data connection for ODBC or OLE DB connections. The function returns an empty string if no **connect** statement has been executed, or after a **disconnect** statement.

```
ConnectionString ()
```

#### FileName

The **FileName** function returns a string containing the name of the table file currently being read, without path or extension.

```
FileName ()
```

#### FileDir

The **FileDir** function returns a string containing the path to the directory of the table file currently being read.

```
FileDir ()
```

#### FileExtension

The **FileExtension** function returns a string containing the extension of the table file currently being read.

```
FileExtension ()
```

#### FileName

The **FileName** function returns a string containing the name of the table file currently being read, without path but including the extension.

```
FileName ()
```

#### FilePath

The **FilePath** function returns a string containing the full path to the table file currently being read.

```
FilePath ()
```

#### FileSize

The **FileSize** function returns an integer containing the size in bytes of the file filename or, if no filename is specified, of the table file currently being read.

**FileSize** ()

### FileTime

The **FileTime** function returns a timestamp in UTC for the date and time of the last modification of the file filename. If no filename is specified, the function will refer to the currently read table file.

**FileTime** ([ filename ])

### GetFolderPath

The **GetFolderPath** function returns the value of the Microsoft Windows SHGetFolderPath function. This function takes as input the name of a Microsoft Windows folder and returns the full path of the folder.

**GetFolderPath** ()

### QvdCreateTime

This script function returns the XML-header timestamp from a QVD file, if any is present, otherwise it returns NULL. In the timestamp, time is provided in UTC.

**QvdCreateTime** (filename)

### QvdFieldName

This script function returns the name of field number **fieldno**, if it exists in a QVD file (otherwise NULL).

**QvdFieldName** (filename , fieldno)

### QvdNoOfFields

This script function returns the number of fields in a QVD file.

**QvdNoOfFields** (filename)

### QvdNoOfRecords

This script function returns the number of records currently in a QVD file.

**QvdNoOfRecords** (filename)

### QvdTableName

This script function returns the name of the table stored in a QVD file.

**QvdTableName** (filename)

## Attribute

This script function returns the value of the meta tags of different media files as text. The following file formats are supported: MP3, WMA, WMV, PNG and JPG. If the file **filename** does not exist, is not a supported file format or does not contain a meta tag named **attributename**, NULL will be returned.

### Syntax:

**Attribute**(filename, attributename)

A large number of meta tags can be read. The examples in this topic show which tags can be read for the respective supported file types.

You can only read meta tags saved in the file according to the relevant specification, for example ID2v3 for MP3 files or EXIF for JPG files, not meta information saved in the **Windows Explorer** (Windows 7) or **File Explorer** (Windows 8.1 and 10).

### Arguments:

- filename: The name of a media file including path, if needed.
  - absolute

**Example: c:\data\**

- relative to the QlikView document path.

**Example: data\**

- attributename: The name of a meta tag.

### Example 1: MP3 files

This script reads all possible MP3 meta tags in folder *MyMusic*.

```
// Script to read MP3 meta tags
for each vExt in 'mp3'
for each vFoundFile in filelist(GetFolderPath('MyMusic') & '*.' & vExt)
FileList:
LOAD FileLongName,
 subfield(FileLongName, '\', -1) as FileShortName,
 num(FileSize(FileLongName), '# ### ### ###', ',', ' ') as FileSize,
 FileTime(FileLongName) as FileTime,
 // ID3v1.0 and ID3v1.1 tags
 Attribute(FileLongName, 'Title') as Title,
 Attribute(FileLongName, 'Artist') as Artist,
 Attribute(FileLongName, 'Album') as Album,
 Attribute(FileLongName, 'Year') as Year,
 Attribute(FileLongName, 'Comment') as Comment,
 Attribute(FileLongName, 'Track') as Track,
 Attribute(FileLongName, 'Genre') as Genre,
 // ID3v2.3 tags
 Attribute(FileLongName, 'AENC') as AENC, // Audio encryption
 Attribute(FileLongName, 'APIC') as APIC, // Attached picture
 Attribute(FileLongName, 'COMM') as COMM, // Comments
 Attribute(FileLongName, 'COMR') as COMR, // Commercial frame
 Attribute(FileLongName, 'ENCR') as ENCR, // Encryption method registration
 Attribute(FileLongName, 'EQUA') as EQUA, // Equalization
 Attribute(FileLongName, 'ETCO') as ETCO, // Event timing codes
 Attribute(FileLongName, 'GEOB') as GEOB, // General encapsulated object
 Attribute(FileLongName, 'GRID') as GRID, // Group identification registration
 Attribute(FileLongName, 'IPLS') as IPLS, // Involved people list
 Attribute(FileLongName, 'LINK') as LINK, // Linked information
 Attribute(FileLongName, 'MCDI') as MCDI, // Music CD identifier
 Attribute(FileLongName, 'MLLT') as MLLT, // MPEG location lookup table
```

```
Attribute(FileLongName, 'OWNE') as OWNE, // Ownership frame
Attribute(FileLongName, 'PRIV') as PRIV, // Private frame
Attribute(FileLongName, 'PCNT') as PCNT, // Play counter
Attribute(FileLongName, 'POPM') as POPM, // Popularimeter
Attribute(FileLongName, 'POSS') as POSS, // Position synchronisation frame
Attribute(FileLongName, 'RBUF') as RBUF, // Recommended buffer size
Attribute(FileLongName, 'RVAD') as RVAD, // Relative volume adjustment
Attribute(FileLongName, 'RVRB') as RVRB, // Reverb
Attribute(FileLongName, 'SYLT') as SYLT, // Synchronized lyric/text
Attribute(FileLongName, 'SYTC') as SYTC, // Synchronized tempo codes
Attribute(FileLongName, 'TALB') as TALB, // Album/Movie/Show title
Attribute(FileLongName, 'TBPM') as TBPM, // BPM (beats per minute)
Attribute(FileLongName, 'TCOM') as TCOM, // Composer
Attribute(FileLongName, 'TCON') as TCON, // Content type
Attribute(FileLongName, 'TCOP') as TCOP, // Copyright message
Attribute(FileLongName, 'TDAT') as TDAT, // Date
Attribute(FileLongName, 'TDLY') as TDLY, // Playlist delay
Attribute(FileLongName, 'TENC') as TENC, // Encoded by
Attribute(FileLongName, 'TEXT') as TEXT, // Lyricist/Text writer
Attribute(FileLongName, 'TFLT') as TFLT, // File type
Attribute(FileLongName, 'TIME') as TIME, // Time
Attribute(FileLongName, 'TIT1') as TIT1, // Content group description
Attribute(FileLongName, 'TIT2') as TIT2, // Title/songname/content description
Attribute(FileLongName, 'TIT3') as TIT3, // Subtitle/Description refinement
Attribute(FileLongName, 'TKEY') as TKEY, // Initial key
Attribute(FileLongName, 'TLAN') as TLAN, // Language(s)
Attribute(FileLongName, 'TLEN') as TLEN, // Length
Attribute(FileLongName, 'TMED') as TMED, // Media type
Attribute(FileLongName, 'TOAL') as TOAL, // Original album/movie/show title
Attribute(FileLongName, 'TOFN') as TOFN, // Original filename
Attribute(FileLongName, 'TOLY') as TOLY, // Original lyricist(s)/text writer(s)
Attribute(FileLongName, 'TOPE') as TOPE, // Original artist(s)/performer(s)
Attribute(FileLongName, 'TORY') as TORY, // Original release year
Attribute(FileLongName, 'TOWN') as TOWN, // File owner/licensee
Attribute(FileLongName, 'TPE1') as TPE1, // Lead performer(s)/Soloist(s)
Attribute(FileLongName, 'TPE2') as TPE2, // Band/orchestra/accompaniment
Attribute(FileLongName, 'TPE3') as TPE3, // Conductor/performer refinement
Attribute(FileLongName, 'TPE4') as TPE4, // Interpreted, remixed, or otherwise modified by
Attribute(FileLongName, 'TPOS') as TPOS, // Part of a set
Attribute(FileLongName, 'TPUB') as TPUB, // Publisher
Attribute(FileLongName, 'TRCK') as TRCK, // Track number/Position in set
Attribute(FileLongName, 'TRDA') as TRDA, // Recording dates
Attribute(FileLongName, 'TRSN') as TRSN, // Internet radio station name
Attribute(FileLongName, 'TRSO') as TRSO, // Internet radio station owner
Attribute(FileLongName, 'TSIZ') as TSIZ, // Size
Attribute(FileLongName, 'TSRC') as TSRC, // ISRC (international standard recording code)
Attribute(FileLongName, 'TSSE') as TSSE, // Software/Hardware and settings used for
encoding
Attribute(FileLongName, 'TYER') as TYER, // Year
Attribute(FileLongName, 'TXXX') as TXXX, // User defined text information frame
Attribute(FileLongName, 'UFID') as UFID, // Unique file identifier
Attribute(FileLongName, 'USER') as USER, // Terms of use
Attribute(FileLongName, 'USLT') as USLT, // Unsynchronized lyric/text transcription
Attribute(FileLongName, 'WCOM') as WCOM, // Commercial information
Attribute(FileLongName, 'WCOP') as WCOP, // Copyright/Legal information
```

```
Attribute(FileLongName, 'WOAF') as WOAF, // Official audio file webpage
Attribute(FileLongName, 'WOAR') as WOAR, // Official artist/performer webpage
Attribute(FileLongName, 'WOAS') as WOAS, // Official audio source webpage
Attribute(FileLongName, 'WORS') as WORS, // Official internet radio station homepage
Attribute(FileLongName, 'WPAY') as WPAY, // Payment
Attribute(FileLongName, 'WPUB') as WPUB, // Publishers official webpage
Attribute(FileLongName, 'WXXX') as WXXX; // User defined URL link frame
LOAD @1:n as FileLongName Inline "$(vFoundFile)" (fix, no labels);
Next vFoundFile
Next vExt
```

### Example 2: JPEG

This script reads all possible EXIF meta tags from JPG files in folder *MyPictures*.

```
// Script to read jpeg Exif meta tags
for each vExt in 'jpg', 'jpeg', 'jpe', 'jfif', 'jif', 'jfi'
for each vFoundFile in filelist(GetFolderPath('MyPictures') & '*.' & vExt)
FileList:
LOAD FileLongName,
 subfield(FileLongName, '\', -1) as FileShortName,
 num(FileSize(FileLongName), '# ### ##', ',', ' ') as FileSize,
 FileTime(FileLongName) as FileTime,
 // ***** Exif Main (IFD0) Attributes *****
 Attribute(FileLongName, 'Imagewidth') as Imagewidth,
 Attribute(FileLongName, 'ImageLength') as ImageLength,
 Attribute(FileLongName, 'BitsPerSample') as BitsPerSample,
 Attribute(FileLongName, 'Compression') as Compression,
 // examples: 1=uncompressed, 2=CCITT, 3=CCITT 3, 4=CCITT 4,
 // 5=LZW, 6=JPEG (old style), 7=JPEG, 8=Deflate, 32773=PackBits RLE,
 Attribute(FileLongName, 'PhotometricInterpretation') as PhotometricInterpretation,
 // examples: 0=whiteIsZero, 1=BlackIsZero, 2=RGB, 3=Palette, 5=CMYK, 6=YCbCr,
 Attribute(FileLongName, 'ImageDescription') as ImageDescription,
 Attribute(FileLongName, 'Make') as Make,
 Attribute(FileLongName, 'Model') as Model,
 Attribute(FileLongName, 'StripOffsets') as StripOffsets,
 Attribute(FileLongName, 'Orientation') as Orientation,
 // examples: 1=TopLeft, 2=TopRight, 3=BottomRight, 4=BottomLeft,

Attribute(FileLongName, 'WMFSDKNeeded') as WMFSDKNeeded,
Attribute(FileLongName, 'IsVBR') as IsVBR,
Attribute(FileLongName, 'ASFLeakyBucketPairs') as ASFLeakyBucketPairs,
Attribute(FileLongName, 'PeakValue') as PeakValue,
Attribute(FileLongName, 'AverageLevel') as AverageLevel;
LOAD @1:n as FileLongName Inline "$(vFoundFile)" (fix, no labels);
Next vFoundFile
Next vExt

```

### Example 4: PNG

This script reads all possible PNG meta tags in folder *MyPictures*.

```

// Script to read PNG meta tags
for each vExt in 'png'
for each vFoundFile in filelist(GetFolderPath('MyPictures') & '*.' & vExt)
FileList:
LOAD FileLongName,
 subfield(FileLongName, '\', -1) as FileShortName,
 num(FileSize(FileLongName), '# ### ##', ',', ',') as FileSize,
 FileTime(FileLongName) as FileTime,
 Attribute(FileLongName, 'Comment') as Comment,
 Attribute(FileLongName, 'Creation Time') as Creation_Time,
 Attribute(FileLongName, 'Source') as Source,
 Attribute(FileLongName, 'Title') as Title,
 Attribute(FileLongName, 'Software') as Software,
 Attribute(FileLongName, 'Author') as Author,
 Attribute(FileLongName, 'Description') as Description,
 Attribute(FileLongName, 'Copyright') as Copyright;
LOAD @1:n as FileLongName Inline "$(vFoundFile)" (fix, no labels);
Next vFoundFile
Next vExt

```

## ConnectionString

The **ConnectionString()** function returns the name of the active data connection for ODBC or OLE DB connections. The function returns an empty string if no **connect** statement has been executed, or after a **disconnect** statement.

### Syntax:

**ConnectionString()**

Examples and results

| Example | Result |
|---------|--------|
|         |        |

### FileBaseName

The **FileBaseName** function returns a string containing the name of the table file currently being read, without path or extension.

#### Syntax:

```
FileBaseName ()
```

#### Examples and results:

##### Examples and results

| Example                                                | Result                                            |
|--------------------------------------------------------|---------------------------------------------------|
| LOAD *, filebasename( ) as X from C:\UserFiles\abc.txt | Will return 'abc' in field X in each record read. |

### FileDir

The **FileDir** function returns a string containing the path to the directory of the table file currently being read.

#### Syntax:

```
FileDir ()
```

#### Examples and results:

##### Examples and results

| Example                                           | Result                                                     |
|---------------------------------------------------|------------------------------------------------------------|
| Load *, filedir( ) as X from C:\UserFiles\abc.txt | Will return 'C:\UserFiles' in field X in each record read. |

### FileExtension

The **FileExtension** function returns a string containing the extension of the table file currently being read.

#### Syntax:

```
FileExtension ()
```

#### Examples and results:

##### Examples and results

| Example                                                 | Result                                            |
|---------------------------------------------------------|---------------------------------------------------|
| LOAD *, FileExtension( ) as X from C:\UserFiles\abc.txt | Will return 'txt' in field X in each record read. |

### FileName

The **FileName** function returns a string containing the name of the table file currently being read, without path but including the extension.

#### Syntax:

```
FileName()
```

#### Examples and results:

##### Examples and results

| Example                                            | Result                                                |
|----------------------------------------------------|-------------------------------------------------------|
| LOAD *, FileName( ) as X from C:\UserFiles\abc.txt | Will return 'abc.txt' in field X in each record read. |

### FilePath

The **FilePath** function returns a string containing the full path to the table file currently being read.

#### Syntax:

```
FilePath()
```

#### Examples and results:

##### Examples and results

| Example                                            | Result                                                             |
|----------------------------------------------------|--------------------------------------------------------------------|
| Load *, FilePath( ) as X from C:\UserFiles\abc.txt | Will return 'C:\UserFiles\abc.txt' in field X in each record read. |

### FileSize

The **FileSize** function returns an integer containing the size in bytes of the file filename or, if no filename is specified, of the table file currently being read.

#### Syntax:

```
FileSize([filename])
```

#### Arguments:

- filename: The name of a file, if necessary including path. If you don't specify a file name, the table file currently being read is used.
  - absolute

**Example: c:\data**

- relative to the QlikView document path.

**Example:** *data1*

- URL address (HTTP or FTP), pointing to a location on the Internet or an intranet.

**Example:** *http://www.qlik.com*

**Examples and results:**

Examples and results

| Example                                   | Result                                                                                             |
|-------------------------------------------|----------------------------------------------------------------------------------------------------|
| LOAD *, FileSize( ) as X<br>from abc.txt; | Will return the size of the specified file (abc.txt) as an integer in field X in each record read. |
| FileSize( 'xyz.xls' )                     | Will return the size of the file xyz.xls.                                                          |

### FileTime

The **FileTime** function returns a timestamp in UTC for the date and time of the last modification of the file filename. If no filename is specified, the function will refer to the currently read table file.

**Syntax:**

```
FileTime([filename])
```

**Arguments:**

- filename: The name of a file, if necessary including path.
  - absolute

**Example:** *c:\data1*

- relative to the QlikView document path.

**Example:** *data1*

- URL address (HTTP or FTP), pointing to a location on the Internet or an intranet.

**Example:** *http://www.qlik.com*

**Examples and results:**

Examples and results

| Example                                   | Result                                                                                                                      |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| LOAD *, FileTime( ) as X<br>from abc.txt; | Will return the date and time of the last modification of the file (abc.txt) as a timestamp in field X in each record read. |
| FileTime( 'xyz.xls' )                     | Will return the timestamp of the last modification of the file xyz.xls.                                                     |

### GetFolderPath

The **GetFolderPath** function returns the value of the Microsoft Windows SHGetFolderPath function. This function takes as input the name of a Microsoft Windows folder and returns the full path of the folder.

#### Syntax:

```
GetFolderPath (foldername)
```

#### Arguments:

GetFolderPath arguments

| Argument   | Description                                                                                                                                                                                                                                               |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| foldername | Name of the Microsoft Windows folder.<br><br>The folder name should not contain any space. Any space in the folder name seen in Windows Explorer should be removed from the folder name.<br><br>Examples:<br><br><i>MyMusic</i><br><br><i>MyDocuments</i> |

#### Examples and results:

The goal of this example is to get the paths of the following Microsoft Windows folders: *MyMusic*, *MyPictures* and *Windows*. Add the example script to your app and reload it.

```
LOAD
 GetFolderPath('MyMusic') as MyMusic,
 GetFolderPath('MyPictures') as MyPictures,
 GetFolderPath('Windows') as Windows
AutoGenerate 1;
```

Once the app is reloaded, the fields *MyMusic*, *MyPictures* and *Windows* are added to the data model. Each field contains the path to the folder defined in input. For example:

- *C:\Users\smu\Music* for the folder *MyMusic*
- *C:\Users\smu\Pictures* for the folder *MyPictures*
- *C:\Windows* for the folder *Windows*

### QvdCreateTime

This script function returns the XML-header timestamp from a QVD file, if any is present, otherwise it returns NULL. In the timestamp, time is provided in UTC.

#### Syntax:

```
QvdCreateTime (filename)
```

### Arguments:

- filename: The name of a QVD file, if necessary including path.

- absolute

**Example:** *c:\data*

- relative to the QlikView document path.

**Example:** *data*

- URL address (HTTP or FTP), pointing to a location on the Internet or an intranet.

**Example:** *http://www.qlik.com*

### Example:

```
QvdCreateTime('MyFile.qvd')
QvdCreateTime('C:\MyDir\MyFile.qvd')
```

### QvdFieldName

This script function returns the name of field number **fieldno**, if it exists in a QVD file (otherwise NULL).

### Syntax:

```
QvdFieldName (filename , fieldno)
```

### Arguments:

- filename: The name of a QVD file, if necessary including path.

- absolute

**Example:** *c:\data*

- relative to the QlikView document path.

**Example:** *data*

- URL address (HTTP or FTP), pointing to a location on the Internet or an intranet.

**Example:** *http://www.qlik.com*

- fieldno: The number of the field (starting at 1) within the table contained in the QVD file.

### Examples:

```
QvdFieldName ('MyFile.qvd', 3)
QvdFieldName ('C:\MyDir\MyFile.qvd', 5)
```

### QvdNoOfFields

This script function returns the number of fields in a QVD file.

#### Syntax:

```
QvdNoOfFields (filename)
```

#### Arguments:

- filename: The name of a QVD file, if necessary including path.

- absolute

**Example:** *c:\data*

- relative to the QlikView document path.

**Example:** *data*

- URL address (HTTP or FTP), pointing to a location on the Internet or an intranet.

**Example:** *http://www.qlik.com*

#### Examples:

```
QvdNoOfFields ('MyFile.qvd')
QvdNoOfFields ('C:\MyDir\MyFile.qvd')
```

### QvdNoOfRecords

This script function returns the number of records currently in a QVD file.

#### Syntax:

```
QvdNoOfRecords (filename)
```

#### Arguments:

- filename: The name of a QVD file, if necessary including path.

- absolute

**Example:** *c:\data*

- relative to the QlikView document path.

**Example:** *data*

- URL address (HTTP or FTP), pointing to a location on the Internet or an intranet.

**Example:** *http://www.qlik.com*

### Examples:

```
QvdNoOfRecords ('MyFile.qvd')
QvdNoOfRecords ('C:\MyDir\MyFile.qvd')
```

### QvdTableName

This script function returns the name of the table stored in a QVD file.

### Syntax:

```
QvdTableName (filename)
```

### Arguments:

- filename: The name of a QVD file, if necessary including path.
  - absolute

**Example:** *c:\data*

- relative to the QlikView document path.

**Example:** *data*

- URL address (HTTP or FTP), pointing to a location on the Internet or an intranet.

**Example:** *http://www.qlik.com*

### Examples:

```
QvdTableName ('MyFile.qvd')
QvdTableName ('C:\MyDir\MyFile.qvd')
```

## Financial functions

Financial functions can be used in the load script and in chart expressions to calculate payments and interest rates.

For all the arguments, cash that is paid out is represented by negative numbers. Cash received is represented by positive numbers.

Listed here are the arguments that are used in the financial functions (excepting the ones beginning with **range-**).

*For all financial functions it is vital that you are consistent when specifying units for **rate** and **nper**. If monthly payments are made on a five-year loan at 6% annual interest, use 0.005 (6%/12) for **rate** and 60 (5\*12) for **nper**. If annual payments are made on the same loan, use 6% for **rate** and 5 for **nper**.*

### Financial functions overview

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

#### FV

This function returns the future value of an investment based on periodic, constant payments and a simple annual interest.

```
FV (rate, nper, pmt [,pv [, type]])
```

#### nPer

This function returns the number of periods for an investment based on periodic, constant payments and a constant interest rate.

```
nPer (rate, pmt, pv [,fv [, type]])
```

#### Pmt

This function returns the payment for a loan based on periodic, constant payments and a constant interest rate. It cannot change over the life of the annuity. A payment is stated as a negative number, for example, -20.

```
Pmt (rate, nper, pv [,fv [, type]])
```

#### PV

This function returns the present value of an investment.

```
PV (rate, nper, pmt [,fv [, type]])
```

#### Rate

This function returns the interest rate per period on annuity. The result has a default number format of **Fix** two decimals and %.

```
Rate (nper, pmt , pv [,fv [, type]])
```

### BlackAndSchole

The Black and Scholes model is a mathematical model for financial market derivative instruments. The formula calculates the theoretical value of an option. In QlikView, the **BlackAndSchole** function returns the value according to the Black and Scholes unmodified formula (European style options).

```
BlackAndSchole (strike , time_left , underlying_price , vol , risk_free_rate , type)
```

**Return data type:** numeric

### Arguments:

BlackAndSchole arguments

| Argument         | Description                                                                                                                   |
|------------------|-------------------------------------------------------------------------------------------------------------------------------|
| strike           | The future purchase price of the stock.                                                                                       |
| time_left        | The number of time periods remaining.                                                                                         |
| underlying_price | The current value of the stock.                                                                                               |
| vol              | The volatility in % per time period.                                                                                          |
| risk_free_rate   | The risk -free rate in % per time period.                                                                                     |
| type             | The type of option:<br><br>'c', 'call' or any non-zero numeric value for call options<br><br>'p', 'put' or 0 for put options. |

### Examples and results:

Examples and results

| Example                                                                                                                                                                                                                                                                           | Result            |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| <p><code>BlackAndSchole(130, 4, 68.5, 0.4, 0.04, 'call')</code></p> <p>This calculates the theoretical price of an option to buy a share that is worth 68.5 today, at a value of 130 in 4 years. A volatility of 40% per year and a risk-free interest rate of 4% is assumed.</p> | Returns<br>11.245 |

## FV

This function returns the future value of an investment based on periodic, constant payments and a simple annual interest.

### Syntax:

```
FV(rate, nper, pmt [,pv [, type]])
```

**Return data type:** numeric. The result has a default number format of money. .

### Arguments:

FV arguments

| Argument | Description                                        |
|----------|----------------------------------------------------|
| rate     | The interest rate per period.                      |
| nper     | The total number of payment periods in an annuity. |

## 9 Script syntax and chart functions

| Argument | Description                                                                                                                                                          |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pmt      | The payment made each period. It cannot change over the life of the annuity. A payment is stated as a negative number, for example, -20.                             |
| pv       | The present value, or lump-sum amount, that a series of future payments is worth right now. If <b>pv</b> is omitted, it is assumed to be 0 (zero).                   |
| type     | Should be 0 if payments are due at the end of the period and 1 if payments are due at the beginning of the period. If <b>type</b> is omitted, it is assumed to be 0. |

### Examples and results:

#### Examples and results

| Example                                                                                                                                                                                                                                                               | Result           |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| <p>You are paying a new household appliance by 36 monthly installments of \$20. The interest rate is 6% per annum. The bill comes at the end of every month. What is the total invested, when the last bill has been paid?</p> <p><code>FV(0.005, 36, -20)</code></p> | Returns \$786.72 |

### nPer

This function returns the number of periods for an investment based on periodic, constant payments and a constant interest rate.

#### Syntax:

```
nPer(rate, pmt, pv [,fv [, type]])
```

**Return data type:** numeric

#### Arguments:

#### nPer arguments

| Argument | Description                                                                                                                                                          |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rate     | The interest rate per period.                                                                                                                                        |
| nper     | The total number of payment periods in an annuity.                                                                                                                   |
| pmt      | The payment made each period. It cannot change over the life of the annuity. A payment is stated as a negative number, for example, -20.                             |
| pv       | The present value, or lump-sum amount, that a series of future payments is worth right now. If <b>pv</b> is omitted, it is assumed to be 0 (zero).                   |
| fv       | The future value, or cash balance, you want to attain after the last payment is made. If <b>fv</b> is omitted, it is assumed to be 0.                                |
| type     | Should be 0 if payments are due at the end of the period and 1 if payments are due at the beginning of the period. If <b>type</b> is omitted, it is assumed to be 0. |

### Examples and results:

#### Examples and results

| Example                                                                                                                                                                                                                                                                                                                         | Result                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| <p>You want to sell a household appliance by monthly installments of \$20. The interest rate is 6% per annum. The bill comes at the end of every month. How many periods are required if the value of the money received after the last bill has been paid should equal \$800?</p> <p><code>nPer(0.005, -20, 0, 800)</code></p> | <p>Returns<br/>36.56</p> |

### Pmt

This function returns the payment for a loan based on periodic, constant payments and a constant interest rate. It cannot change over the life of the annuity. A payment is stated as a negative number, for example, -20.

```
Pmt(rate, nper, pv [,fv [, type]])
```

**Return data type:** numeric. The result has a default number format of money. .

To find the total amount paid over the duration of the loan, multiply the returned **pmt** value by **nper**.

### Arguments:

#### Pmt arguments

| Argument | Description                                                                                                                                                          |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rate     | The interest rate per period.                                                                                                                                        |
| nper     | The total number of payment periods in an annuity.                                                                                                                   |
| pv       | The present value, or lump-sum amount, that a series of future payments is worth right now. If <b>pv</b> is omitted, it is assumed to be 0 (zero).                   |
| fv       | The future value, or cash balance, you want to attain after the last payment is made. If <b>fv</b> is omitted, it is assumed to be 0.                                |
| type     | Should be 0 if payments are due at the end of the period and 1 if payments are due at the beginning of the period. If <b>type</b> is omitted, it is assumed to be 0. |

### Examples and results:

#### Examples and results

| Example                                                                                                                                                                                   | Result                          |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|
| <p>The following formula returns the monthly payment on a \$20,000 loan at an annual rate of 10 percent, that must be paid off in 8 months:</p> <p><code>Pmt(0.1/12, 8, 20000)</code></p> | <p>Returns -<br/>\$2,594.66</p> |

## 9 Script syntax and chart functions

| Example                                                                                                                      | Result                  |
|------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| For the same loan, if payment is due at the beginning of the period, the payment is:<br><code>Pmt(0.1/12,8,20000,0,1)</code> | Returns -<br>\$2,573.21 |

### PV

This function returns the present value of an investment.

```
PV(rate, nper, pmt [,fv [, type]])
```

**Return data type:** numeric. The result has a default number format of money. .

The present value is the total amount that a series of future payments is worth right now. For example, when borrowing money, the loan amount is the present value to the lender.

#### Arguments:

##### PV arguments

| Argument | Description                                                                                                                                                          |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rate     | The interest rate per period.                                                                                                                                        |
| nper     | The total number of payment periods in an annuity.                                                                                                                   |
| pmt      | The payment made each period. It cannot change over the life of the annuity. A payment is stated as a negative number, for example, -20.                             |
| fv       | The future value, or cash balance, you want to attain after the last payment is made. If <b>fv</b> is omitted, it is assumed to be 0.                                |
| type     | Should be 0 if payments are due at the end of the period and 1 if payments are due at the beginning of the period. If <b>type</b> is omitted, it is assumed to be 0. |

#### Examples and results:

##### Examples and results

| Example                                                                                                                                                                                     | Result                |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| What is the present value of a debt, when you have to pay \$100 at the end of each month during a five-year period, given an interest rate of 7%?<br><code>PV(0.07/12,12*5,-100,0,0)</code> | Returns<br>\$5,050.20 |

### Rate

This function returns the interest rate per period on annuity. The result has a default number format of **Fix** two decimals and %.

#### Syntax:

```
Rate(nper, pmt , pv [,fv [, type]])
```

**Return data type:** numeric.

The **rate** is calculated by iteration and can have zero or more solutions. If the successive results of **rate** do not converge, a NULL value will be returned.

**Arguments:**

### Rate arguments

| Argument | Description                                                                                                                                                          |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| nper     | The total number of payment periods in an annuity.                                                                                                                   |
| pmt      | The payment made each period. It cannot change over the life of the annuity. A payment is stated as a negative number, for example, -20.                             |
| pv       | The present value, or lump-sum amount, that a series of future payments is worth right now. If <b>pv</b> is omitted, it is assumed to be 0 (zero).                   |
| fv       | The future value, or cash balance, you want to attain after the last payment is made. If <b>fv</b> is omitted, it is assumed to be 0.                                |
| type     | Should be 0 if payments are due at the end of the period and 1 if payments are due at the beginning of the period. If <b>type</b> is omitted, it is assumed to be 0. |

**Examples and results:**

### Examples and results

| Example                                                                                                                     | Result        |
|-----------------------------------------------------------------------------------------------------------------------------|---------------|
| What is the interest rate of a five-year \$10,000 annuity loan with monthly payments of \$300?<br><br>rate(60, -300, 10000) | Returns 2.00% |

## Formatting functions

The formatting functions impose the display format on the input numeric fields or expressions. Depending on data type, you can specify the characters for the the decimal separator, thousands separator, and so on.

The functions all return a dual value with both the string and the number value, but can be thought of as performing a number-to-string conversion. **Dual()** is a special case, but the other formatting functions take the numeric value of the input expression and generate a string representing the number.

In contrast, the interpretation functions do the opposite: they take string expressions and evaluate them as numbers, specifying the format of the resulting number.

The functions can be used both in load scripts and chart expressions.

*For reasons of clarity, all number representations are given with a decimal point as the decimal separator.*

### Formatting functions overview

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

#### Date

**Date()** formats an expression as a date using the format set in the system variables in the load script, or the operating system, or a format string, if supplied.

```
Date (number[, format])
```

#### Dual

**Dual()** combines a number and a string into a single record, such that the number representation of the record can be used for sorting and calculation purposes, while the string value can be used for display purposes

```
Dual (text, number)
```

#### Interval

**Interval()** formats a number as a time interval using the format in the system variables in the load script, or the operating system, or a format string, if supplied.

```
Interval (number[, format])
```

#### Money

**Money()** formats an expression numerically as a money value, in the format set in the system variables set in the load script, or in the operating system, unless a format string is supplied, and optional decimal and thousands separators.

```
Money (number[, format[, dec_sep [, thou_sep]])
```

#### Num

**Num()** formats a number, that is it converts the numeric value of the input to display text using the format specified in the second parameter. If the second parameter is omitted, it uses the decimal and thousand separators set in the data load script. Custom decimal and thousand separator symbols are optional parameters.

```
Num (number[, format[, dec_sep [, thou_sep]])
```

#### Time

**Time()** formats an expression as a time value, in the time format set in the system variables in the load script, or in the operating system, unless a format string is supplied.

```
Time (number[, format])
```

### Timestamp

**TimeStamp()** formats an expression as a date and time value, in the timestamp format set in the system variables in the load script, or in the operating system, unless a format string is supplied.

```
TimeStamp (number[, format])
```

### Date

**Date()** formats an expression as a date using the format set in the system variables in the load script, or the operating system, or a format string, if supplied.

#### Syntax:

```
Date (number[, format])
```

**Return data type:** dual

#### Arguments:

##### Date arguments

| Argument | Description                                                                                                                                 |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------|
| number   | The number to be formatted.                                                                                                                 |
| format   | String describing the format of the resulting string. If no format string is supplied, the date format set in the operating system is used. |

#### Examples:

The examples below assume the following default settings:

- Date setting 1: YY-MM-DD
- Date setting 2: M/D/YY

#### Example 1:

```
Date(A)
where A=35648
```

##### Example 1 results

| Results | Setting 1 | Setting 2 |
|---------|-----------|-----------|
| String: | 97-08-06  | 8/6/97    |
| Number: | 35648     | 35648     |

#### Example 2:

```
Date(A, 'YY.MM.DD')
where A=35648
```

## 9 Script syntax and chart functions

---

Example 2 results

| Results | Setting 1 | Setting 2 |
|---------|-----------|-----------|
| String: | 97.08.06  | 97.08.06  |
| Number: | 35648     | 35648     |

### Example 3:

```
Date(A, 'DD.MM.YYYY')
where A=35648.375
```

Example 3 results

| Results | Setting 1  | Setting 2  |
|---------|------------|------------|
| String: | 06.08.1997 | 06.08.1997 |
| Number: | 35648.375  | 35648.375  |

### Example 4:

```
Date(A, 'YY.MM.DD')
where A=8/6/97
```

Example 4 results

| Results | Setting 1      | Setting 2 |
|---------|----------------|-----------|
| String: | NULL (nothing) | 97.08.06  |
| Number: | NULL           | 35648     |

## Dual

**Dual()** combines a number and a string into a single record, such that the number representation of the record can be used for sorting and calculation purposes, while the string value can be used for display purposes

### Syntax:

```
Dual (text, number)
```

**Return data type:** dual

### Arguments:

Dual arguments

| Argument | Description                                                                  |
|----------|------------------------------------------------------------------------------|
| text     | The string value to be used in combination with the number argument.         |
| number   | The number to be used in combination with the string in the string argument. |

---

## 9 Script syntax and chart functions

---

In QlikView, all field values are potentially dual values. This means that the field values can have both a numeric value and a textual value. An example is a date that could have a numeric value of 40908 and the textual representation '2011-12-31'.

When several data items read into one field have different string representations but the same valid number representation, they will all share the first string representation encountered.

*The **dual** function is typically used early in the script, before other data is read into the field concerned, in order to create that first string representation, which will be shown in list boxes.*

### Example 1:

Add the following examples to your script and run it.

```
Load dual (NameDay,NumDay) as DayOfWeek inline
[NameDay,NumDay
Monday,0
Tuesday,1
Wednesday,2
Thursday,3
Friday,4
Saturday,5
Sunday,6];
```

The field DayOfWeek can be used in a chart, as a dimension, for example. In a table with the week days are automatically sorted into their correct number sequence, instead of alphabetical order.

### Example 2:

```
Load Dual('Q' & Ceil(Month(Now())/3), Ceil(Month(Now())/3)) as Quarter AutoGenerate 1;
```

This example finds the current quarter. It is displayed as Q1 when the **Now()** function is run in the first three months of the year, Q2 for the second three months, and so on. However, when used in sorting, the field Quarter will behave as its numerical value: 1 to 4.

### Example 3:

```
Dual('Q' & Ceil(Month(Date)/3), Ceil(Month(Date)/3)) as Quarter
```

As in the previous example, the field Quarter is created with the text values 'Q1' to 'Q4', and assigned the numeric values 1 to 4. In order to use this in the script the values for Date must be loaded.

### Example 4:

```
Dual(weekYear(Date) & '-w' & week(Date), weekStart(Date)) as YearWeek
```

This example create sa field YearWeek with text values of the form '2012-W22' and at the same time, assigns a numeric value corresponding to the date number of the first day of the week, for example: 41057. In order to use this in the script the values for Date must be loaded.

### Interval

**Interval()** formats a number as a time interval using the format in the system variables in the load script, or the operating system, or a format string, if supplied.

Intervals may be formatted as a time, as days or as a combination of days, hours, minutes, seconds and fractions of seconds.

#### Syntax:

```
Interval(number[, format])
```

**Return data type:** dual

#### Arguments:

Interval arguments

| Argument | Description                                                                                                                                                                         |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| number   | The number to be formatted.                                                                                                                                                         |
| format   | String describing how the resulting interval string is to be formatted. If omitted, the short date format, time format, and decimal separator set in the operating system are used. |

#### Examples:

The examples below assume the following default settings:

- Date format setting 1: YY-MM-DD
- Date format setting 2: hh:mm:ss
- Number decimal separator: .

Examples and results

| Example                                                                         | String    | Number  |
|---------------------------------------------------------------------------------|-----------|---------|
| Interval( A )<br>where A=0.375                                                  | 09:00:00  | 0.375   |
| Interval( A )<br>where A=1.375                                                  | 33:00:00  | 1.375   |
| Interval( A, 'D hh:mm' )<br>where A=1.375                                       | 1 09:00   | 1.375   |
| Interval( A-B, 'D hh:mm' )<br>where A=97-08-06 09:00:00 and B=96-08-06 00:00:00 | 365 09:00 | 365.375 |

### Num

**Num()** formats a number, that is it converts the numeric value of the input to display text using the format specified in the second parameter. If the second parameter is omitted, it uses the decimal and thousand separators set in the data load script. Custom decimal and thousand separator symbols are optional

parameters.

### Syntax:

```
Num(number[, format[, dec_sep [, thou_sep]])
```

### Return data type: dual

The Num function returns a dual value with both the string and the numeric value. The function takes the numeric value of the input expression and generates a string representing the number.

### Arguments:

Num arguments

| Argument | Description                                                                                                                                                   |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| number   | The number to be formatted.                                                                                                                                   |
| format   | String specifying how the resulting string is to be formatted. If omitted, the decimal and thousand separators that are set in the data load script are used. |
| dec_sep  | String specifying the decimal number separator. If omitted, the value of the variable DecimalSep that is set in the data load script is used.                 |
| thou_sep | String specifying the thousands number separator. If omitted, the value of the variable ThousandSep that is set in the data load script is used.              |

### Example:

The following table shows the results when field A equals 35648.312.

| Results                     |                                                        |
|-----------------------------|--------------------------------------------------------|
| A                           | Result                                                 |
| Num(A)                      | 35648.312 (depends on environment variables in script) |
| Num(A, '0.0', ',')          | 35648.3                                                |
| Num(A, '0,00', ',')         | 35648,31                                               |
| Num(A, '#,##0.0', ',', ',') | 35,648.3                                               |
| Num(A, '# ##0', ',', ',')   | 35 648                                                 |

### Example:

Add this example script to your app and run it.

Then build a straight table with Field1 and Field2 as dimensions.

```
Sheet1:
let result= Num(pi(), '0,00');
Load * inline
[Field1; Field2
9; 8,2
1; $(result)
```

```
](delimiter is ';');
```

Field1 contains the values 1 and 9.

Field2 contains the values 3,14 and 8,2.

### Money

**Money()** formats an expression numerically as a money value, in the format set in the system variables set in the load script, or in the operating system, unless a format string is supplied, and optional decimal and thousands separators.

#### Syntax:

```
Money (number[, format[, dec_sep[, thou_sep]])
```

**Return data type:** dual

#### Arguments:

##### Money arguments

| Argument | Description                                                          |
|----------|----------------------------------------------------------------------|
| number   | The number to be formatted.                                          |
| format   | String describing how the resulting money string is to be formatted. |
| dec_sep  | String specifying the decimal number separator.                      |
| thou_sep | String specifying the thousands number separator.                    |

If the **format**, **dec\_sep**, and **thou\_sep** arguments are omitted, the currency format set in the operating system is used when formatting each specific part of the output. The operating system settings are automatically included as system variables upon creation of the script, thus making sure that these are consistent throughout the entire application.

These system variables are **MoneyFormat**, **MoneyDecimalSep**, and **MoneyThousandSep**, and map to the **format**, **dec\_sep**, and **thou\_sep** function arguments respectively.

#### Examples:

The examples below assume the following default settings:

- MoneyFormat setting 1: kr ##0,00, MoneyThousandSep'
- MoneyFormat setting 2: \$ #,##0.00, MoneyThousandSep','

#### Example 1:

```
Money(A)
where A=35648
```

## 9 Script syntax and chart functions

Example 1 results

| Results | Setting 1    | Setting 2    |
|---------|--------------|--------------|
| String: | kr 35 648,00 | \$ 35,648.00 |
| Number: | 35648.00     | 35648.00     |

### Example 2:

```
Money(A, '#,##0 ¥', '.' , ',')
where A=3564800
```

Example 2 results

| Results | Setting 1   | Setting 2   |
|---------|-------------|-------------|
| String: | 3,564,800 ¥ | 3,564,800 ¥ |
| Number: | 3564800     | 3564800     |

## Time

**Time()** formats an expression as a time value, in the time format set in the system variables in the load script, or in the operating system, unless a format string is supplied.

### Syntax:

```
Time(number[, format])
```

**Return data type:** dual

### Arguments:

Time arguments

| Argument | Description                                                                                                                                                                    |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| number   | The number to be formatted.                                                                                                                                                    |
| format   | String describing how the resulting time string is to be formatted. If omitted, the short date format, time format, and decimal separator set in the operating system is used. |

### Examples:

The examples below assume the following default settings:

- Time format setting 1: hh:mm:ss
- Time format setting 2: hh.mm.ss

### Example 1:

```
Time(A)
where A=0.375
```

## 9 Script syntax and chart functions

---

Example 1 results

| Results | Setting 1 | Setting 2 |
|---------|-----------|-----------|
| String: | 09:00:00  | 09.00.00  |
| Number: | 0.375     | 0.375     |

### Example 2:

Time( A )  
where A=35648.375

Example 2 results

| Results | Setting 1 | Setting 2 |
|---------|-----------|-----------|
| String: | 09:00:00  | 09.00.00  |
| Number: | 35648.375 | 35648.375 |

### Example 3:

Time( A, 'hh-mm' )  
where A=0.99999

Example 3 results

| Results | Setting 1 | Setting 2 |
|---------|-----------|-----------|
| String: | 23-59     | 23-59     |
| Number: | 0.99999   | 0.99999   |

## Timestamp

**TimeStamp()** formats an expression as a date and time value, in the timestamp format set in the system variables in the load script, or in the operating system, unless a format string is supplied.

### Syntax:

```
TimeStamp(number[, format])
```

**Return data type:** dual

### Arguments:

Timestamp arguments

| Argument | Description                                                                                                                                                                         |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| number   | The number to be formatted.                                                                                                                                                         |
| format   | String describing how the resulting timestamp string is to be formatted. If omitted, the short date format, time format, and decimal separator set in the operating system is used. |

### Examples:

The examples below assume the following default settings:

- TimestampFormat setting 1: YY-MM-DD hh:mm:ss
- TimestampFormat setting 2: M/D/YY hh:mm:ss

#### Example 1:

```
Timestamp(A)
where A=35648.375
```

Example 1 results

| Results | Setting 1         | Setting 2       |
|---------|-------------------|-----------------|
| String: | 97-08-06 09:00:00 | 8/6/97 09:00:00 |
| Number: | 35648.375         | 35648.375       |

#### Example 2:

```
Timestamp(A, 'YYYY-MM-DD hh.mm')
where A=35648
```

Example 2 results

| Results | Setting 1        | Setting 2        |
|---------|------------------|------------------|
| String: | 1997-08-06 00.00 | 1997-08-06 00.00 |
| Number: | 35648            | 35648            |

## General numeric functions

In these general numeric functions, the arguments are expressions where **x** should be interpreted as a real valued number. All functions can be used in both load scripts and chart expressions.

### General numeric functions overview

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

bitcount

**BitCount()** finds how many bits in the binary equivalent of a number are set to 1. That is, the function returns the number of set bits in **integer\_number**, where **integer\_number** is interpreted as a signed 32-bit integer.

```
BitCount(integer_number)
```

div

**Div()** returns the integer part of the arithmetic division of the first argument by the second argument. Both parameters are interpreted as real numbers, that is, they do not have to be integers.

```
Div(integer_number1, integer_number2)
```

fabs

**Fabs()** returns the absolute value of **x**. The result is a positive number.

```
Fabs(x)
```

fact

**Fact()** returns the factorial of a positive integer **x**.

```
Fact(x)
```

frac

**Frac()** returns the fraction to the right of the decimal point of **x**, where **x** is a real number.

```
Frac(x)
```

sign

**Sign()** returns 1, 0 or -1 depending on whether **x** is a positive number, 0, or a negative number.

```
Sign(x)
```

### Combination and permutation functions

combin

**Combin()** returns the number of combinations of **q** elements that can be picked from a set of **p** items. As represented by the formula:  $\text{combin}(p,q) = p! / q!(p-q)!$  The order in which the items are selected is insignificant.

```
Combin(p, q)
```

permut

**Permut()** returns the number of permutations of **q** elements that can be selected from a set of **p** items. As represented by the formula:  $\text{Permut}(p,q) = (p)! / (p - q)!$  The order in which the items are selected is significant.

```
Permut(p, q)
```

### Modulo functions

fmod

**fmod()** is a modulo function that returns the remainder part of the division of the first argument (the dividend) by the second argument (the divisor). The result is a real number. Both arguments are interpreted as real numbers, that is, they do not have to be integers.

```
Fmod(a, b)
```

mod

**Mod()** is a modulo function that returns the non-negative remainder of an integer division. The first argument is the dividend, the second argument is the divisor, Both arguments must be integer values.

```
Mod(integer_number1, integer_number2)
```

### Parity functions

even

**Even()** returns True (-1), if **integer\_number** is an even integer or zero. It returns False (0), if **integer\_number** is an odd integer, and NULL if **integer\_number** is not an integer.

```
Even(integer_number)
```

odd

**Odd()** returns True (-1), if **integer\_number** is an odd integer or zero. It returns False (0), if **integer\_number** is an even integer, and NULL if **integer\_number** is not an integer.

```
Odd(integer_number)
```

### Rounding functions

ceil

**Ceil()** rounds **x** up to the nearest multiple of **step** [+ **offset**]. The default value of **offset** is 0.

```
Ceil(x[, step[, offset]])
```

floor

**Floor()** rounds **x** down to the nearest multiple of **step** [+ **offset**]. The default value of **offset** is 0.

```
Floor(x[, step[, offset]])
```

round

**Round()** returns the result of rounding **x** up or down to the nearest multiple of **step** [+ **offset**]. The default value of **offset** is 0.

```
Round(x [, step [, offset]])
```

### BitCount

**BitCount()** finds how many bits in the binary equivalent of a number are set to 1. That is, the function returns the number of set bits in **integer\_number**, where **integer\_number** is interpreted as a signed 32-bit integer.

**Syntax:**

```
BitCount(integer_number)
```

**Return data type:** integer

**Examples and results:**

- `BitCount ( 3 )`: 3 is binary 101, therefore this returns 2
- `BitCount ( -1 )`: -1 is 64 ones in binary, therefore this returns 64

### Ceil

**Ceil()** rounds **x** up to the nearest multiple of **step** [+ **offset**]. The default value of **offset** is 0.

Compare with the **floor** function, which rounds input numbers down.

**Syntax:**

```
Ceil(x[, step[, offset]])
```

**Return data type:** integer

**Examples and results:**

- `Ceil( 2.4 )`: returns 3
- `Ceil( 2.6 )`: returns 3
- `Ceil( 3.88 , 0.1 )`: returns 3.9
- `Ceil( 3.88 , 5 )`: returns 5
- `Ceil( 1.1 , 1 )`: returns 2
- `Ceil( 1.1 , 1 , 0.5 )`: returns 1.5
- `Ceil( 1.1 , 1 , -0.01 )`: returns 1.99

### Combin

**Combin()** returns the number of combinations of **q** elements that can be picked from a set of **p** items. As represented by the formula:  $\text{combin}(p,q) = \frac{p!}{q!(p-q)!}$  The order in which the items are selected is insignificant.

**Syntax:**

```
Combin(p, q)
```

**Return data type:** integer

**Limitations:**

Non-integer arguments will be truncated.

**Examples and results:**

- How many combinations of 7 numbers can be picked from a total of 35 lottery numbers?  
`Combin( 35,7 )` returns 6,724,520

### Div

**Div()** returns the integer part of the arithmetic division of the first argument by the second argument. Both parameters are interpreted as real numbers, that is, they do not have to be integers.

#### Syntax:

```
Div(integer_number1, integer_number2)
```

**Return data type:** integer

#### Examples and results:

- `Div( 7, 2 )`: returns 3
- `Div( 7.1, 2.3 )`: returns 3
- `Div( 9, 3 )`: returns 3
- `Div( -4, 3 )`: returns -1
- `Div( 4, -3 )`: returns -1
- `Div( -4, -3 )`: returns 1

### Even

**Even()** returns True (-1), if **integer\_number** is an even integer or zero. It returns False (0), if **integer\_number** is an odd integer, and NULL if **integer\_number** is not an integer.

#### Syntax:

```
Even(integer_number)
```

**Return data type:** Boolean

#### Examples and results:

- `Even( 3 )`: returns 0, False
- `Even( 2 * 10 )`: returns -1, True
- `Even( 3.14 )`: returns NULL

### Fabs

**Fabs()** returns the absolute value of **x**. The result is a positive number.

#### Syntax:

```
fabs(x)
```

**Return data type:** numeric

#### Examples and results:

- `fabs( 2.4 )`: returns 2.4
- `fabs( -3.8 )`: returns 3.8

### Fact

**Fact()** returns the factorial of a positive integer **x**.

**Syntax:**

```
Fact (x)
```

**Return data type:** integer

**Limitations:**

If the number **x** is not an integer, it will be truncated. Non-positive numbers will return NULL.

**Examples and results:**

- `Fact( 1 )`: returns 1
- `Fact( 5 )`: returns 120 (  $1 * 2 * 3 * 4 * 5 = 120$  )
- `Fact( -5 )`: returns NULL

### Floor

**Floor()** rounds **x** down to the nearest multiple of **step** [+ **offset**]. The default value of **offset** is 0.

Compare with the **ceil** function, which rounds input numbers up.

**Syntax:**

```
Floor (x[, step[, offset]])
```

**Return data type:** numeric

**Examples and results:**

- `Floor( 2,4 )`: returns 0
- `Floor( 4,2 )`: returns 4
- `Floor( 3.88 , 0.1 )`: returns 3.8
- `Floor( 3.88 , 5 )`: returns 0
- `Floor( 1.1 , 1 )`: returns 1
- `Floor( 1.1 , 1 , 0.5 )`: returns 0.5

### Fmod

**fmod()** is a modulo function that returns the remainder part of the division of the first argument (the dividend) by the second argument (the divisor). The result is a real number. Both arguments are interpreted as real numbers, that is, they do not have to be integers.

**Syntax:**

```
fmod (a, b)
```

**Return data type:** numeric

**Examples and results:**

- `fmod( 7, 2 )`: returns 1
- `fmod( 7.5, 2 )`: returns 1.5
- `fmod( 9, 3 )`: returns 0
- `fmod( -4, 3 )`: returns -1
- `fmod( 4, -3 )`: returns 1
- `fmod( -4, -3 )`: returns -1

### Frac

**Frac()** returns the fraction to the right of the decimal point of **x**, where **x** is a real number.

The fraction is defined in such a way that  $\text{Frac}(x) + \text{Floor}(x) = x$ . In simple terms this means that the fractional part of a positive number is the difference between the number (**x**) and the integer that precedes it.

For example: The fractional part of 11.43 =  $11.43 - 11 = 0.43$

For a negative number, say -1.4,  $\text{Floor}(-1.4) = -2$ , which produces the following result:

The fractional part of -1.4 =  $1.4 - (-2) = -1.4 + 2 = 0.6$

**Syntax:**

```
Frac(x)
```

**Return data type:** numeric

**Examples and results:**

- `Frac( 11.43 )`: returns 0.43
- `Frac( -1.4 )`: returns 0.6

### Mod

**Mod()** is a modulo function that returns the non-negative remainder of an integer division. The first argument is the dividend, the second argument is the divisor, Both arguments must be integer values.

**Syntax:**

```
Mod(integer_number1, integer_number2)
```

**Return data type:** integer

**Limitations:**

**integer\_number2** must be greater than 0.

### Examples and results:

- `Mod( 7, 2 )`: returns 1
- `Mod( 7.5, 2 )`: returns NULL
- `Mod( 9, 3 )`: returns 0
- `Mod( -4, 3 )`: returns 2
- `Mod( 4, -3 )`: returns NULL
- `Mod( -4, -3 )`: returns NULL

### Odd

**Odd()** returns True (-1), if **integer\_number** is an odd integer or zero. It returns False (0), if **integer\_number** is an even integer, and NULL if **integer\_number** is not an integer.

#### Syntax:

```
Odd(integer_number)
```

**Return data type:** Boolean

### Examples and results:

- `Odd( 3 )`: returns -1, True
- `Odd( 2 * 10 )`: returns 0, False
- `Odd( 3.14 )`: returns NULL

### Permut

**Permut()** returns the number of permutations of **q** elements that can be selected from a set of **p** items. As represented by the formula:  $\text{Permut}(p, q) = \frac{p!}{(p - q)!}$ . The order in which the items are selected is significant.

#### Syntax:

```
Permut(p, q)
```

**Return data type:** integer

#### Limitations:

Non-integer arguments will be truncated.

### Examples and results:

- In how many ways could the gold, silver and bronze medals be distributed after a 100 m final with 8 participants?  
`Permut( 8, 3 )` returns 336

### Round

**Round()** returns the result of rounding **x** up or down to the nearest multiple of **step** [+ **offset**]. The default value of **offset** is 0. The default value of **step** is 1.

If **x** is exactly in the middle of an interval, it is rounded upwards.

#### Syntax:

```
Round(x[, step[, offset]])
```

**Return data type:** numeric

*If you are rounding a floating point number you may experience results that are erroneous. These mostly insignificant rounding errors are due to that floating point numbers are represented by a finite number of binary digits. That results in QlikView calculating with a number that is already rounded. If it is critical to have correct rounding, a workaround is to multiply the numbers to convert them to integers.*

#### Examples and results:

- `Round( 3.8 )`: returns 4.
- `Round( 3.8, 4 )`: returns 4.
- `Round( 2.5 )`: returns 3. Rounded up because 2.5 is exactly half of the default step interval.
- `Round( 2, 4 )`: returns 4. Rounded up because 2 is exactly half of the step interval of 4.
- `Round( 2, 6 )`: returns 0. Rounded down because 2 is less than half of the step interval of 6.
- `Round( 3.88 , 0.1 )`: returns 3.9.
- `Round( 3.88 , 5 )`: returns 5.
- `Round( 1.1 , 1 , 0.5 )`: returns 1.5.

### Sign

**Sign()** returns 1, 0 or -1 depending on whether **x** is a positive number, 0, or a negative number.

#### Syntax:

```
Sign(x)
```

**Return data type:** numeric

#### Limitations:

If no numeric value is found, NULL is returned.

#### Examples and results:

- `Sign( 66 )`: returns 1
- `Sign( 0 )`: returns 0

- `Sign( - 234 )`: returns -1

### Interpretation functions

The interpretation functions evaluate the contents of input text fields or expressions, and impose a specified data format on the resulting numeric value. With these functions, you can specify the format of the number, in accordance with its data type, including attributes such as: decimal separator, thousands separator, and date format.

The interpretation functions all return a dual value with both the string and the number value, but can be thought of as performing a string-to-number conversion. The functions take the text value of the input expression and generate a number representing the string.

In contrast, the formatting functions do the opposite: they take numeric expressions and evaluate them as strings, specifying the display format of the resulting text.

If no interpretation functions are used, QlikView interprets the data as a mix of numbers, dates, times, time stamps and strings, using the default settings for number format, date format, and time format, defined by script variables and by the operating system.

All interpretation functions can be used in both load scripts and chart expressions.

*For reasons of clarity, all number representations are given with a decimal point as the decimal separator.*

### Interpretation functions overview

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

#### **Date#**

**Date#** converts a text string to a numerical date by applying the provided date format pattern, or if omitted by the default date format pattern. If the format code is omitted, the default date format set in the operating system is used.

```
Date#(text[, format])
```

#### **Interval#**

**Interval#()** evaluates a text expression as a time interval in the format set in the operating system, by default, or in the format specified in the second argument, if supplied.

```
Interval#(text[, format])
```

#### **Money#**

**Money#()** converts a text string to a money value, in the format set in the load script or the operating system, unless a format string is supplied. Custom decimal and thousand separator symbols are optional parameters.

```
Money#(text[, format[, dec_sep[, thou_sep]]])
```

### Num#

**Num#()** interprets a text string as a numerical value, that is it converts the input string to a number using the format specified in the second parameter. If the second parameter is omitted, it uses the decimal and thousand separators set in the data load script. Custom decimal and thousand separator symbols are optional parameters.

```
Num# (text[, format[, dec_sep[, thou_sep]])
```

### Text

**Text()** forces the expression to be treated as text, even if a numeric interpretation is possible.

```
Text (expr)
```

### Time#

**Time#()** evaluates an expression as a time value, in the time format set in the load script or the operating system, unless a format string is supplied..

```
Time# (text[, format])
```

### Timestamp#

**Timestamp#()** evaluates an expression as a date and time value, in the timestamp format set in the load script or the operating system, unless a format string is supplied.

```
Timestamp# (text[, format])
```

### Date#

**Date#** converts a text string to a numerical date by applying the provided date format pattern, or if omitted by the default date format pattern.

#### Syntax:

```
Date# (text[, format])
```

**Return data type:** dual

#### Arguments:

Date# arguments

| Argument | Description                                                                                                                                     |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| text     | The text string to be evaluated.                                                                                                                |
| format   | String describing the format that should be used to interpret the text string. If omitted, the date format set in the operating system is used. |

#### Example:

The following example uses the date format **M/D/YYYY**. The date format is specified in the **SET DateFormat** statement at the top of the data load script.

Add this example script to your app and run it.

```
Load *,
Num(Date#(StringDate)) as Date;
LOAD * INLINE [
StringDate
8/7/97
8/6/1997
];
```

If you create a table with **StringDate** and **Date** as dimensions, the results are as follows:

Example 1 results

| StringDate | Date  |
|------------|-------|
| 8/7/97     | 35649 |
| 8/6/1997   | 35648 |

### Interval#

**Interval#()** evaluates a text expression as a time interval in the format set in the operating system, by default, or in the format specified in the second argument, if supplied.

#### Syntax:

```
Interval#(text[, format])
```

**Return data type:** dual

#### Arguments:

| Argument | Description                                                                                                                                                                                                             |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| text     | The text string to be evaluated.                                                                                                                                                                                        |
| format   | String describing the expected input format to use when converting the string to a numeric interval.<br><br>If omitted, the short date format, time format, and decimal separator set in the operating system are used. |

The **interval#** function converts a text time interval to a numeric equivalent.

#### Example:

The examples below assume the following operating system settings:

- Short date format: YY-MM-DD
- Time format: M/D/YY
- Number decimal separator: .

### Examples and results

| Example                                        | Result |
|------------------------------------------------|--------|
| Interval#( A, 'D hh:mm' )<br>where A='1 09:00' | 1.375  |

### Money#

**Money#()** converts a text string to a money value, in the format set in the load script or the operating system, unless a format string is supplied. Custom decimal and thousand separator symbols are optional parameters.

#### Syntax:

```
Money#(text[, format[, dec_sep [, thou_sep]]])
```

**Return data type:** dual

#### Arguments:

#### Money# arguments

| Argument | Description                                                                                                                                                                   |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| text     | The text string to be evaluated.                                                                                                                                              |
| format   | String describing the expected input format to use when converting the string to a numeric interval.<br><br>If omitted, the money format set in the operating system is used. |
| dec_sep  | String specifying the decimal number separator. If omitted, the MoneyDecimalSep value set in the load script is used.                                                         |
| thou_sep | String specifying the thousands number separator. If omitted, the MoneyThousandSep value set in the load script is used.                                                      |

The **money#** function generally behaves just like the **num#** function but takes its default values for decimal and thousand separator from the script variables for money format or the system settings for currency.

The examples below assume the two following operating system settings:

- Money format default setting 1: kr # ##0,00
- Money format default setting 2: \$ #,##0.00

#### Example 1:

```
Money#(A , '# ##0,00 kr')
where A=35 648,37 kr
```

Example 1 results

| Results | Setting 1    | Setting 2    |
|---------|--------------|--------------|
| String: | 35 648.37 kr | 35 648.37 kr |
| Number: | 35648.37     | 3564837      |

### Example 2:

Money#( A, ' \$#', '.', ',' )  
 where A= \$35,648.37

Example 2 results

| Results | Setting 1   | Setting 2   |
|---------|-------------|-------------|
| String: | \$35,648.37 | \$35,648.37 |
| Number: | 35648.37    | 35648.37    |

### Num#

**Num#()** interprets a text string as a numerical value, that is it converts the input string to a number using the format specified in the second parameter. If the second parameter is omitted, it uses the decimal and thousand separators set in the data load script. Custom decimal and thousand separator symbols are optional parameters.

#### Syntax:

```
Num# (text[, format[, dec_sep [, thou_sep]]])
```

#### Return data type: dual

The **Num#()** function returns a dual value with both the string and the numeric value. The function takes the textual representation of the input expression and generates a number. It does not change the format of the number: the output is formatted in the same way as the input.

#### Arguments:

Num# arguments

| Argument | Description                                                                                                                                                     |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| text     | The text string to be evaluated.                                                                                                                                |
| format   | String specifying the number format used in the first parameter. If omitted, the decimal and thousand separators that are set in the data load script are used. |
| dec_sep  | String specifying the decimal number separator. If omitted, the value of the variable DecimalSep that is set in the data load script is used.                   |
| thou_sep | String specifying the thousands number separator. If omitted, the value of the variable ThousandSep that is set in the data load script is used.                |

### Example:

The following table shows the result of `Num#( A, '#', '.', ',')` for different values of A.

| A            | String representation | Results                                           |
|--------------|-----------------------|---------------------------------------------------|
|              |                       | Numeric value (here displayed with decimal point) |
| 35,648.31    | 35,648.31             | 35648.31                                          |
| 35 648.312   | 35 648.312            | 35648.312                                         |
| 35.648,3123  | 35.648,3123           | -                                                 |
| 35 648,31234 | 35 648,31234          | -                                                 |

### Text

`Text()` forces the expression to be treated as text, even if a numeric interpretation is possible.

#### Syntax:

```
Text (expr)
```

**Return data type:** dual

#### Examples and results:

Examples and results

| Example                   | Result  | Result value    |
|---------------------------|---------|-----------------|
| Text( A )<br>where A=1234 | String: | 1234            |
|                           | Number: | -               |
| Text( pi( ) )             | String: | 3.1415926535898 |
|                           | Number: | -               |

### Time#

`Time#()` evaluates an expression as a time value, in the time format set in the load script or the operating system, unless a format string is supplied..

#### Syntax:

```
time#(text[, format])
```

**Return data type:** dual

**Arguments:**

Time# arguments

| Argument | Description                                                                                                                                                                               |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| text     | The text string to be evaluated.                                                                                                                                                          |
| format   | String describing the format that should be used to interpret the text string. If omitted, the short date format, time format, and decimal separator set in the operating system is used. |

Examples and results:

The examples below assume the two following operating system settings:

- Time format default setting 1: hh:mm:ss
- Time format default setting 2: hh.mm.ss

**Example 1:**

```
time#(A)
where A=09:00:00
```

| Results | Setting 1 | Setting 2 |
|---------|-----------|-----------|
| String: | 09:00:00  | 09:00:00  |
| Number: | 0.375     | -         |

**Example 2:**

```
time#(A, 'hh.mm')
where A=09.00
```

| Results | Setting 1 | Setting 2 |
|---------|-----------|-----------|
| String: | 09.00     | 09.00     |
| Number: | 0.375     | 0.375     |

### Timestamp#

**Timestamp#()** evaluates an expression as a date and time value, in the timestamp format set in the load script or the operating system, unless a format string is supplied.

**Syntax:**

```
timestamp#(text[, format])
```

**Return data type:** dual

**Arguments:**

Timestamp# arguments

| Argument | Description                                                                                                                                                                                                                     |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| text     | The text string to be evaluated.                                                                                                                                                                                                |
| format   | String describing the format that should be used to interpret the text string. If omitted, the short date format, time format, and decimal separator set in the operating system is used. ISO 8601 is supported for timestamps. |

**Example:**

The following example uses the date format **M/D/YYYY**. The date format is specified in the **SET DateFormat** statement at the top of the data load script.

Add this example script to your app and run it.

```
Load *,
Timestamp(Timestamp#(String)) as TS;
LOAD * INLINE [
String
2015-09-15T12:13:14
1952-10-16T13:14:00+0200
1109-03-01T14:15
];
```

If you create a table with **String** and **TS** as dimensions, the results are as follows:

Example 1 results

| String                   | TS                     |
|--------------------------|------------------------|
| 2015-09-15T12:13:14      | 9/15/2015 12:13:14 PM  |
| 1952-10-16T13:14:00+0200 | 10/16/1952 11:14:00 AM |
| 1109-03-01T14:15         | 3/1/1109 2:15:00 PM    |

### Inter-record functions

Inter-record functions are used:

- In the load script, when a value from previously loaded records of data is needed for the evaluation of the current record.
- In a chart expression, when another value from the data set of a chart is needed.

Sorting on y-values in charts or sorting by expression columns in tables is not allowed when an inter-record chart function is used in any of the chart's expressions. These sort alternatives are therefore automatically disabled. When you use an inter-record chart function in a visualization or table, the sorting of the visualization will revert back to the sorted input to the inter-record function. This limitation does not apply to the equivalent script function, if there is one.

From QlikView 12.00, suppression of zero values is activated by default. If you want to retain the same behavior as in QlikView 11.20 when using inter-record functions, you should disable the suppression of zero values. Open **Chart Properties**, go to the **Presentation** tab, and deselect **Suppress Zero-Values**.

Self-referencing expression definitions can only reliably be made in tables with fewer than 100 rows, but this may vary depending on the hardware that the Qlik engine is running on.

### Row functions

These functions can only be used in chart expressions.

Above

**Above()** evaluates an expression at a row above the current row within a column segment in a table. The row for which it is calculated depends on the value of **offset**, if present, the default being the row directly above. For charts other than tables, **Above()** evaluates for the row above the current row in the chart's straight table equivalent.

```
Above ([TOTAL [<fld{,fld}>]] expr [, offset [,count]])
```

Below

**Below()** evaluates an expression at a row below the current row within a column segment in a table. The row for which it is calculated depends on the value of **offset**, if present, the default being the row directly below. For charts other than tables, **Below()** evaluates for the row below the current column in the chart's straight table equivalent.

```
Below ([TOTAL [<fld{,fld}>]] expression [, offset [,count]])
```

Bottom

**Bottom()** evaluates an expression at the last (bottom) row of a column segment in a table. The row for which it is calculated depends on the value of **offset**, if present, the default being the bottom row. For charts other than tables, the evaluation is made on the last row of the current column in the chart's straight table equivalent.

```
Bottom ([TOTAL [<fld{,fld}>]] expr [, offset [,count]])
```

### Top

**Top()** evaluates an expression at the first (top) row of a column segment in a table. The row for which it is calculated depends on the value of **offset**, if present, the default being the top row. For charts other than tables, the **Top()** evaluation is made on the first row of the current column in the chart's straight table equivalent.

```
Top ([TOTAL [<fld{,fld}>]] expr [, offset [,count]])
```

### NoOfRows

**NoOfRows()** returns the number of rows in the current column segment in a table. For bitmap charts, **NoOfRows()** returns the number of rows in the chart's straight table equivalent.

```
NoOfRows ([TOTAL])
```

## Column functions

These functions can only be used in chart expressions.

### Column

**Column()** returns the value found in the column corresponding to **ColumnNo** in a straight table, disregarding dimensions. For example **Column(2)** returns the value of the second measure column.

```
Column - chart function(ColumnNo)
```

### Dimensionality

**Dimensionality()** returns the number of dimensions for the current row. In the case of pivot tables, the function returns the total number of dimension columns that have non-aggregation content, that is, do not contain partial sums or collapsed aggregates.

```
Dimensionality ()
```

### Secondarydimensionality

**Secondarydimensionality()** returns the number of dimension pivot table rows that have non-aggregation content, that is, do not contain partial sums or collapsed aggregates. This function is the equivalent of the **dimensionality()** function for horizontal pivot table dimensions.

```
Secondarydimensionality ()
```

## Field functions

### FieldIndex

**FieldIndex()** returns the position of the field value **value** in the field **field\_name** (by load order).

```
FieldIndex(field_name , value)
```

### FieldValue

**FieldValue()** returns the value found in position **elem\_no** of the field **field\_name** (by load order).

```
FieldValue(field_name , elem_no)
```

### FieldValueCount

**FieldValueCount()** is an **integer** function that finds the number of distinct values in a field.

```
FieldValueCount (field_name)
```

### Pivot table functions

These functions can only be used in chart expressions.

After

**After()** returns the value of an expression evaluated with a pivot table's dimension values as they appear in the column after the current column within a row segment in the pivot table.

```
After ([TOTAL] expression [, offset [,n]])
```

Before

**Before()** returns the value of an expression evaluated with a pivot table's dimension values as they appear in the column before the current column within a row segment in the pivot table.

```
Before ([TOTAL] expression [, offset [,n]])
```

First

**First()** returns the value of an expression evaluated with a pivot table's dimension values as they appear in the first column of the current row segment in the pivot table. This function returns NULL in all chart types except pivot tables.

```
First ([TOTAL] expression [, offset [,n]])
```

Last

**Last()** returns the value of an expression evaluated with a pivot table's dimension values as they appear in the last column of the current row segment in the pivot table. This function returns NULL in all chart types except pivot tables.

```
Last ([TOTAL] expression [, offset [,n]])
```

ColumnNo

**ColumnNo()** returns the number of the current column within the current row segment in a pivot table. The first column is number 1.

```
ColumnNo ([TOTAL])
```

NoOfColumns

**NoOfColumns()** returns the number of columns in the current row segment in a pivot table.

```
NoOfColumns ([TOTAL])
```

### Inter-record functions in the load script

Exists

**Exists()** determines whether a specific field value has already been loaded into the field in the load script. The function returns TRUE or FALSE, so can be used in the **where** clause of a **LOAD** statement or an **IF** function.

```
Exists (field [, expression]
```

### LookUp

**LookUp()** looks into a table that is already loaded and returns the value of **field\_name** corresponding to the first occurrence of the value **match\_field\_value** in the field **match\_field\_name**. The table can be the current table or another table previously loaded.

```
LookUp (fieldname, matchfieldname, matchfieldvalue [, tablename])
```

### Peek

**Peek()** finds the value of a field in a table for a row that has already been loaded or that exists in internal memory. The row number can be specified, as can the table.

```
Peek (fieldname [, row [, tablename]])
```

### Previous

**Previous()** finds the value of the **expr** expression using data from the previous input record. In the first record of an internal table, the function will return NULL.

```
Previous (expression)
```

### Above

**Above()** evaluates an expression at a row above the current row within a column segment in a table. The row for which it is calculated depends on the value of **offset**, if present, the default being the row directly above. For charts other than tables, **Above()** evaluates for the row above the current row in the chart's straight table equivalent.

### Syntax:

```
Above ([TOTAL] expr [, offset [,count]])
```

**Return data type:** dual

### Arguments:

- **expr:** The expression or field containing the data to be measured.
- **offset:** Specifying an **offset n**, greater than 0, moves the evaluation of the expression **n** rows further up from the current row. Specifying an offset of 0 will evaluate the expression on the current row. Specifying a negative offset number makes the **Above** function work like the **Below** function with the corresponding positive offset number.
- **count:** By specifying a third argument **count** greater than 1, the function will return a range of **count** values, one for each of **count** table rows counting upwards from the original cell. In this form, the function can be used as an argument to any of the special range functions. *Range functions (page 1477)*
- **TOTAL:** If the table is one-dimensional or if the qualifier **TOTAL** is used as argument, the current column segment is always equal to the entire column.

On the first row of a column segment, a NULL value is returned, as there is no row above it.

A column segment is defined as a consecutive subset of cells having the same values for the dimensions in the current sort order. Inter-record chart functions are computed in the column segment excluding the right-most dimension in the equivalent straight table chart. If there is only one dimension in the chart, or if the TOTAL qualifier is specified, the expression evaluates across full table.

If the table or table equivalent has multiple vertical dimensions, the current column segment will include only rows with the same values as the current row in all dimension columns, except for the column showing the last dimension in the inter-field sort order.

### Limitations:

- Recursive calls will return NULL.
- Sorting on y-values in charts or sorting by expression columns in tables is not allowed when this chart function is used in any of the chart's expressions. These sort alternatives are therefore automatically disabled. When you use this chart function in a visualization or table, the sorting of the visualization will revert back to the sorted input to this function.

### Examples and results:

#### Example 1:

Example table output

| Customer   | Sum (Sales) | Above(Sum (Sales)) | Sum(Sales) + Above(Sum (Sales)) | Above offset 3 | Higher? |
|------------|-------------|--------------------|---------------------------------|----------------|---------|
| -          | 2566        | -                  | -                               | -              | -       |
| Astrida    | 587         | -                  | -                               | -              | -       |
| Betacab    | 539         | 587                | 1126                            | -              | -       |
| Canutility | 683         | 539                | 1222                            | -              | Higher  |
| Divadip    | 757         | 683                | 1440                            | 1344           | Higher  |

In the representation of the table chart shown in this example, the table is created from the dimension **Customer** and the measures: `sum(Sales)` and `Above(Sum(Sales))`.

The column `Above(Sum(Sales))` returns NULL for the **Customer** row containing **Astrida**, because there is no row above it. The result for the row **Betacab** shows the value of `Sum(Sales)` for **Astrida**, the result for **Canutility** shows the value for `Sum(Sales)` for **Betacab**, and so on.

For the column labeled `Sum(Sales)+Above(Sum(Sales))`, the row for **Betacab** shows the result of the addition of the `Sum(Sales)` values for the rows **Betacab + Astrida** (539+587). The result for the row **Canutility** shows the result of the addition of `Sum(Sales)` values for **Canutility + Betacab** (683+539).

## 9 Script syntax and chart functions

The measure labeled **Above offset 3** created using the expression `sum(Sales)+Above(Sum(Sales), 3)` has the argument **offset**, set to 3, and has the effect of taking the value in the row three rows above the current row. It adds the **Sum(Sales)** value for the current **Customer** to the value for the **Customer** three rows above. The values returned for the first three **Customer** rows are null.

The table also shows more complex measures: one created from `sum(Sales)+Above(Sum(Sales))` and one labeled **Higher?**, which is created from `IF(Sum(Sales)>Above(Sum(Sales)), 'Higher')`.

*This function can also be used in charts other than tables, for example bar charts.*

*For other chart types, convert the chart to the straight table equivalent so you can easily interpret which row the function relates to.*

### Example 2:

In the representations of the table charts shown in this example, more dimensions have been added to the charts: **Month** and **Product**. For charts with more than one dimension, the results of expressions containing the **Above**, **Below**, **Top**, and **Bottom** functions depend on the order in which the column dimensions are sorted by QlikView. QlikView evaluates the functions based on the column segments that result from the dimension that is sorted last. The column sort order is controlled under **Sort** and is not necessarily the order in which the columns appear in a table.

In the following representation of the table chart for Example 2, the last-sorted dimension is **Month**, so the **Above** function evaluates based on months. There is a series of results for each **Product** value for each month (**Jan** to **Aug**) - a column segment. This is followed by a series for the next column segment: for each **Month** for the next **Product**. There will be a column segment for each **Customer** value for each **Product**.

Example table output

| Customer | Product | Month | Sum(Sales) | Above(Sum(Sales)) |
|----------|---------|-------|------------|-------------------|
| -        | -       | -     | 2566       | -                 |
| Astrida  | AA      | Jan   | 46         | -                 |
| Astrida  | AA      | Feb   | 60         | 46                |
| Astrida  | AA      | Mar   | 70         | 60                |
| Astrida  | AA      | Apr   | 13         | 70                |
| Astrida  | AA      | May   | 78         | 13                |
| Astrida  | AA      | Jun   | 20         | 78                |
| Astrida  | AA      | Jul   | 45         | 20                |
| Astrida  | AA      | Aug   | 65         | 45                |

### Example 3:

In the representation of the table chart for Example 3, the last sorted dimension is **Product**. This is done by moving the dimension Product to position 3 in the Sorting tab in the properties panel. The **Above** function is evaluated for each **Product**, and because there are only two products, **AA** and **BB**, there is only one non-null result in each series. In row **BB** for the month **Jan**, the value for **Above(Sum(Sales))**, is 46. For row **AA**, the value is null. The value in each row **AA** for any month will always be null, as there is no value of **Product** above AA. The second series is evaluated on **AA** and **BB** for the month **Feb**, for the **Customer** value, **Astrida**. When all the months have been evaluated for **Astrida**, the sequence is repeated for the second **Customer** Betacab, and so on.

Example table output

| Customer | Product | Month | Sum(Sales) | Above(Sum(Sales)) |
|----------|---------|-------|------------|-------------------|
| -        | -       | -     | 2566       | -                 |
| Astrida  | AA      | Jan   | 46         | -                 |
| Astrida  | BB      | Jan   | 46         | 46                |
| Astrida  | AA      | Feb   | 60         | -                 |
| Astrida  | BB      | Feb   | 60         | 60                |
| Astrida  | AA      | Mar   | 70         | -                 |
| Astrida  | BB      | Mar   | 70         | 70                |
| Astrida  | AA      | Apr   | 13         | -                 |
| Astrida  | BB      | Apr   | 13         | 13                |

### Example 4:

The Above function can be used as input to the range functions. For example: `RangeAvg (Above(Sum(Sales),1,3))`.

In the arguments for the Above() function, offset is set to 1 and count is set to 3. The function finds the results of the expression `Sum(Sales)` on the three rows immediately above the current row in the column segment (where there is a row). These three values are used as input to the `RangeAvg()` function, which finds the average of the values in the supplied range of numbers.

A table with Customer as dimension gives the following results for the `RangeAvg()` expression.

Example table output

| Customer   | RangeAvg (Above(Sum(Sales),1,3)) |
|------------|----------------------------------|
| Astrida    | -                                |
| Betacab    | 587                              |
| Canutility | 563                              |
| Divadip    | 603                              |

### Data used in examples:

Monthnames:

```
LOAD * INLINE [
Month, Monthnumber
Jan, 1
Feb, 2
Mar, 3
Apr, 4
May, 5
Jun, 6
Jul, 7
Aug, 8
Sep, 9
Oct, 10
Nov, 11
Dec, 12
];
```

Sales2013:

```
crosstable (Month, Sales) LOAD * inline [
Customer|Jan|Feb|Mar|Apr|May|Jun|Jul|Aug|Sep|Oct|Nov|Dec
Astrida|46|60|70|13|78|20|45|65|78|12|78|22
Betacab|65|56|22|79|12|56|45|24|32|78|55|15
Canutility|77|68|34|91|24|68|57|36|44|90|67|27
Divadip|57|36|44|90|67|27|57|68|47|90|80|94
] (delimiter is '|');
```

To get the months to sort in the correct order, when you create your charts, go to the **Sort** tab of the chart properties, and mark the checkbox **Expression** under **Sort by**. In the expression box write `Monthnumber`.

### Below

**Below()** evaluates an expression at a row below the current row within a column segment in a table. The row for which it is calculated depends on the value of **offset**, if present, the default being the row directly below. For charts other than tables, **Below()** evaluates for the row below the current column in the chart's straight table equivalent.

### Syntax:

```
Below([TOTAL] expression [, offset [,count]])
```

**Return data type:** dual

### Arguments:

- **expr:** The expression or field containing the data to be measured.
- **offset:** Specifying an **offset n**, greater than 0, moves the evaluation of the expression **n** rows further up from the current row. Specifying an offset of 0 will evaluate the expression on the current row. Specifying a negative offset number makes the **Above** function work like the **Below** function with the corresponding positive offset number.
- **count:** By specifying a third argument **count** greater than 1, the function will return a range of **count** values, one for each of **count** table rows counting upwards from the original cell. In this form, the function can be used as an argument to any of the special range functions. *Range functions (page 1477)*

## 9 Script syntax and chart functions

- **TOTAL**: If the table is one-dimensional or if the qualifier **TOTAL** is used as argument, the current column segment is always equal to the entire column.

On the last row of a column segment, a NULL value is returned, as there is no row below it.

A column segment is defined as a consecutive subset of cells having the same values for the dimensions in the current sort order. Inter-record chart functions are computed in the column segment excluding the right-most dimension in the equivalent straight table chart. If there is only one dimension in the chart, or if the **TOTAL** qualifier is specified, the expression evaluates across full table.

If the table or table equivalent has multiple vertical dimensions, the current column segment will include only rows with the same values as the current row in all dimension columns, except for the column showing the last dimension in the inter-field sort order.

### Limitations:

- Recursive calls will return NULL.
- Sorting on y-values in charts or sorting by expression columns in tables is not allowed when this chart function is used in any of the chart's expressions. These sort alternatives are therefore automatically disabled. When you use this chart function in a visualization or table, the sorting of the visualization will revert back to the sorted input to this function.

### Examples and results:

#### Example 1:

Example table output

| Customer   | Sum (Sales) | Below(Sum (Sales)) | Sum(Sales) + Below(Sum (Sales)) | Below offset 3 | Higher? |
|------------|-------------|--------------------|---------------------------------|----------------|---------|
| -          | 2566        | -                  | -                               | 1344           | -       |
| Astrida    | 587         | 539                | 1126                            | -              | Higher  |
| Betacab    | 539         | 683                | 1222                            | -              | -       |
| Canutility | 683         | 757                | 1440                            | -              | -       |
| Divadip    | 757         | -                  | -                               | -              | -       |

In the representation of the table chart shown in for Example 1, the table is created from the dimension **Customer** and the measures: `sum(Sales)` and `below(Sum(Sales))`.

The column **Below(Sum(Sales))** returns NULL for the **Customer** row containing **Divadip**, because there is no row below it. The result for the row **Canutility** shows the value of `Sum(Sales)` for **Divadip**, the result for **Betacab** shows the value for `Sum(Sales)` for **Canutility**, and so on.

## 9 Script syntax and chart functions

The table also shows more complex measures, which you can see in the columns labeled: `sum(Sales)+Below(Sum(Sales))`, **Below +Offset 3**, and **Higher?**. These expressions work as described in the following paragraphs.

For the column labeled **Sum(Sales)+Below(Sum(Sales))**, the row for **Astrida** shows the result of the addition of the **Sum(Sales)** values for the rows **Betacab + Astrida** (539+587). The result for the row **Betacab** shows the result of the addition of **Sum(Sales)** values for **Canutility + Betacab** (539+683).

The measure labeled **Below +Offset 3** created using the expression `sum(Sales)+Below(Sum(Sales), 3)` has the argument **offset**, set to 3, and has the effect of taking the value in the row three rows below the current row. It adds the **Sum(Sales)** value for the current **Customer** to the value from the **Customer** three rows below. The values for the lowest three **Customer** rows are null.

The measure labeled **Higher?** is created from the expression: `IF(Sum(Sales)>Below(Sum(Sales)), 'Higher')`. This compares the values of the current row in the measure **Sum(Sales)** with the row below it. If the current row is a greater value, the text "Higher" is output.

*This function can also be used in charts other than tables, for example bar charts.*

*For other chart types, convert the chart to the straight table equivalent so you can easily interpret which row the function relates to.*

For charts with more than one dimension, the results of expressions containing the **Above**, **Below**, **Top**, and **Bottom** functions depend on the order in which the column dimensions are sorted by QlikView. QlikView evaluates the functions based on the column segments that result from the dimension that is sorted last. The column sort order is controlled under **Sort** and is not necessarily the order in which the columns appear in a table. Please refer to Example 2 in the **Above** function for further details.

### Example 2:

The **Below** function can be used as input to the range functions. For example: `RangeAvg (Below(Sum(Sales),1,3))`.

In the arguments for the **Below()** function, offset is set to 1 and count is set to 3. The function finds the results of the expression **Sum(Sales)** on the three rows immediately below the current row in the column segment (where there is a row). These three values are used as input to the `RangeAvg()` function, which finds the average of the values in the supplied range of numbers.

A table with **Customer** as dimension gives the following results for the expression.

Example table output

| Customer   | RangeAvg (Below(Sum(Sales),1,3)) |
|------------|----------------------------------|
| Astrida    | 659.67                           |
| Betacab    | 720                              |
| Canutility | 757                              |
| Divadip    | -                                |

### Data used in examples:

Monthnames:

```
LOAD * INLINE [
Month, Monthnumber
Jan, 1
Feb, 2
Mar, 3
Apr, 4
May, 5
Jun, 6
Jul, 7
Aug, 8
Sep, 9
Oct, 10
Nov, 11
Dec, 12
];
```

Sales2013:

```
crosstable (Month, Sales) LOAD * inline [
Customer|Jan|Feb|Mar|Apr|May|Jun|Jul|Aug|Sep|Oct|Nov|Dec
Astrida|46|60|70|13|78|20|45|65|78|12|78|22
Betacab|65|56|22|79|12|56|45|24|32|78|55|15
Canutility|77|68|34|91|24|68|57|36|44|90|67|27
Divadip|57|36|44|90|67|27|57|68|47|90|80|94
] (delimiter is '|');
```

To get the months to sort in the correct order, when you create your charts, go to the **Sort** tab of the chart properties, and mark the checkbox **Expression** under **Sort by**. In the expression box write `Monthnumber`.

### Bottom

**Bottom()** evaluates an expression at the last (bottom) row of a column segment in a table. The row for which it is calculated depends on the value of **offset**, if present, the default being the bottom row. For charts other than tables, the evaluation is made on the last row of the current column in the chart's straight table equivalent.

#### Syntax:

```
Bottom([TOTAL] expr [, offset [,count]])
```

**Return data type:** dual

#### Arguments:

- **expr:** The expression or field containing the data to be measured.
- **offset:** Specifying an **offset n**, greater than 0, moves the evaluation of the expression **n** rows further up from the current row. Specifying an offset of 0 will evaluate the expression on the current row. Specifying a negative offset number makes the **Above** function work like the **Below** function with the corresponding positive offset number.
- **count:** By specifying a third argument **count** greater than 1, the function will return a range of **count** values, one for each of **count** table rows counting upwards from the original cell. In this form, the function can be used as an argument to any of the special range functions. *Range functions (page 1477)*

## 9 Script syntax and chart functions

- **TOTAL**: If the table is one-dimensional or if the qualifier **TOTAL** is used as argument, the current column segment is always equal to the entire column.

A column segment is defined as a consecutive subset of cells having the same values for the dimensions in the current sort order. Inter-record chart functions are computed in the column segment excluding the right-most dimension in the equivalent straight table chart. If there is only one dimension in the chart, or if the **TOTAL** qualifier is specified, the expression evaluates across full table.

If the table or table equivalent has multiple vertical dimensions, the current column segment will include only rows with the same values as the current row in all dimension columns, except for the column showing the last dimension in the inter-field sort order.

### Limitations:

- Recursive calls will return NULL.
- Sorting on y-values in charts or sorting by expression columns in tables is not allowed when this chart function is used in any of the chart's expressions. These sort alternatives are therefore automatically disabled. When you use this chart function in a visualization or table, the sorting of the visualization will revert back to the sorted input to this function.

### Examples and results:

#### Example 1:

Example table output

| Customer   | Sum (Sales) | Bottom(Sum (Sales)) | Sum(Sales) + Bottom(Sum (Sales)) | Bottom offset 3 |
|------------|-------------|---------------------|----------------------------------|-----------------|
| -          | 2566        | 757                 | 3323                             | 3105            |
| Astrida    | 587         | 757                 | 1344                             | 1126            |
| Betacab    | 539         | 757                 | 1296                             | 1078            |
| Canutility | 683         | 757                 | 1440                             | 1222            |
| Divadip    | 757         | 757                 | 1514                             | 1296            |

In the representation of the table chart shown in this example, the table is created from the dimension **Customer** and the measures: `sum(Sales)` and `bottom(Sum(Sales))`.

The column **Bottom(Sum(Sales))** returns 757 for the all rows because this is the value of the bottom row: **Divadip**.

## 9 Script syntax and chart functions

The table also shows more complex measures: one created from `Sum(Sales)+Bottom(Sum(Sales))` and one labeled **Bottom offset 3**, which is created using the expression `Sum(Sales)+Bottom(Sum(Sales), 3)` and has the argument **offset** set to 3. It adds the **Sum(Sales)** value for the current row to the value from the third row from the bottom row, that is, the current row plus the value for **Betacab**.

### Example 2:

In the representations of table charts shown in this example, more dimensions have been added to the charts: **Month** and **Product**. For charts with more than one dimension, the results of expressions containing the **Above**, **Below**, **Top**, and **Bottom** functions depend on the order in which the column dimensions are sorted by QlikView. QlikView evaluates the functions based on the column segments that result from the dimension that is sorted last. The column sort order is controlled under **Sort** and is not necessarily the order in which the columns appear in a table.

In the first table, the expression is evaluated based on **Month**, and in the second table it is evaluated based on **Product**. The measure **End value** contains the expression `Bottom(Sum(Sales))`. The bottom row for **Month** is Dec, and the value for Dec both the values of **Product** shown in the table is 22. (Some rows are not shown, to save space.)

Example first table output

| Customer | Product | Month | Sum(Sales) | End value |
|----------|---------|-------|------------|-----------|
| -        | -       | -     | 2566       | -         |
| Astrida  | AA      | Jan   | 46         | 22        |
| Astrida  | AA      | Feb   | 60         | 22        |
| Astrida  | AA      | Mar   | 70         | 22        |
| ...      | ...     | ...   | ...        | ...       |
| Astrida  | AA      | Sep   | 78         | 22        |
| Astrida  | AA      | Oct   | 12         | 22        |
| Astrida  | AA      | Nov   | 78         | 22        |
| Astrida  | AA      | Dec   | 22         | 22        |
| Astrida  | BB      | Jan   | 46         | 22        |

Example second table output

| Customer | Product | Month | Sum(Sales) | End value |
|----------|---------|-------|------------|-----------|
|          |         |       | 2566       | -         |
| Astrida  | AA      | Jan   | 46         | 46        |
| Astrida  | BB      | Jan   | 46         | 46        |
| Astrida  | AA      | Feb   | 60         | 60        |
| Astrida  | BB      | Feb   | 60         | 60        |

## 9 Script syntax and chart functions

| Customer | Product | Month | Sum(Sales) | End value |
|----------|---------|-------|------------|-----------|
| Astrida  | AA      | Mar   | 70         | 70        |
| Astrida  | BB      | Mar   | 70         | 70        |
| Astrida  | AA      | Apr   | 13         | 13        |
| Astrida  | BB      | Apr   | 13         | 13        |

Please refer to Example 2 in the **Above** function for further details.

### Example 3:

The **Bottom** function can be used as input to the range functions. For example: `RangeAvg (Bottom(Sum(Sales),1,3))`.

In the arguments for the **Bottom()** function, offset is set to 1 and count is set to 3. The function finds the results of the expression **Sum(Sales)** on the three rows starting with the row above the bottom row in the column segment (because offset=1), and the two rows above that (where there is a row). These three values are used as input to the `RangeAvg()` function, which finds the average of the values in the supplied range of numbers.

A table with **Customer** as dimension gives the following results for the `RangeAvg()` expression.

Example table output

| Customer   | RangeAvg (Bottom(Sum(Sales),1,3)) |
|------------|-----------------------------------|
| Astrida    | 659.67                            |
| Betacab    | 659.67                            |
| Canutility | 659.67                            |
| Divadip    | 659.67                            |

### Data used in examples:

```
Monthnames:
LOAD * INLINE [
Month, Monthnumber
Jan, 1
Feb, 2
Mar, 3
Apr, 4
May, 5
Jun, 6
Jul, 7
Aug, 8
Sep, 9
Oct, 10
Nov, 11
Dec, 12
];
sales2013:
crosstable (Month, Sales) LOAD * inline [
```

```
Customer|Jan|Feb|Mar|Apr|May|Jun|Jul|Aug|Sep|Oct|Nov|Dec
Astrida|46|60|70|13|78|20|45|65|78|12|78|22
Betacab|65|56|22|79|12|56|45|24|32|78|55|15
Canutility|77|68|34|91|24|68|57|36|44|90|67|27
Divadip|57|36|44|90|67|27|57|68|47|90|80|94
] (delimiter is '|');
```

To get the months to sort in the correct order, when you create your charts, go to the **Sort** tab of the chart properties, and mark the checkbox **Expression** under **Sort by**. In the expression box write `Monthnumber`.

### Column - chart function

**Column()** returns the value found in the column corresponding to **ColumnNo** in a straight table, disregarding dimensions. For example **Column(2)** returns the value of the second measure column.

#### Syntax:

```
Column(ColumnNo)
```

**Return data type:** dual

#### Arguments:

- **ColumnNo:** Column number of a column in the table containing a measure.

*The Column() function disregards dimension columns.*

#### Limitations:

- Sorting on y-values in charts or sorting by expression columns in tables is not allowed when this chart function is used in any of the chart's expressions. These sort alternatives are therefore automatically disabled. When you use this chart function in a visualization or table, the sorting of the visualization will revert back to the sorted input to this function.
- If **ColumnNo** references a column for which there is no measure, a NULL value is returned.
- Recursive calls will return NULL.

### Examples and results:

#### Example script results

| Example                                                                                                                                                                                                                                                                                                                           | Result                                                                                                                                                                                                                                                                                                                           |

| A        | AA      | 16        | 4         | 64          | 505               | 12.67   |
| A        | BB      | 9         | 9         | 81          | 505               | 16.04   |
| B        | BB      | 10        | 5         | 50          | 505               | 9.90    |
| B        | CC      | 20        | 2         | 40          | 505               | 7.92    |
| B        | DD      | 25        | -         | 0           | 505               | 0.00    |
| C        | AA      | 15        | 8         | 120         | 505               | 23.76   |
| C        | CC      | 19        | -         | 0           | 505               | 0.00    |

#### Percentage of sales for selected customer

| Customer | Product | UnitPrice | UnitSales | Order Value | Total Sales Value | % Sales |
|----------|---------|-----------|-----------|-------------|-------------------|---------|
| A        | AA      | 15        | 10        | 150         | 295               | 50.85   |
| A        | AA      | 16        | 4         | 64          | 295               | 21.69   |
| A        | BB      | 9         | 9         | 81          | 295               | 27.46   |

### Data used in examples:

ProductData:  
LOAD \* inline [

```
Customer|Product|UnitSales|UnitPrice
Astrida|AA|4|16
Astrida|AA|10|15
Astrida|BB|9|9
Betacab|BB|5|10
Betacab|CC|2|20
Betacab|DD||25
Canutility|AA|8|15
Canutility|CC||19
] (delimiter is '|');
```

### Dimensionality

**Dimensionality()** returns the number of dimensions for the current row. In the case of pivot tables, the function returns the total number of dimension columns that have non-aggregation content, that is, do not contain partial sums or collapsed aggregates.

#### Syntax:

```
Dimensionality ()
```

**Return data type:** integer

#### Limitations:

This function is only available in charts. The number of dimensions in all rows, except the total which will be 0, will be returned. For all chart types, except pivot table it will return the number of dimensions in all rows except the total, which will be 0.

Sorting on y-values in charts or sorting by expression columns in tables is not allowed when this chart function is used in any of the chart's expressions. These sort alternatives are therefore automatically disabled. When you use this chart function in a visualization or table, the sorting of the visualization will revert back to the sorted input to this function.

#### Examples:

A typical use for dimensionality is when you want to make a calculation only if there is a value present for a dimension.

Examples and results

| Example                                                                                                                                        | Result |
|------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| For a table containing the dimension UnitSales, you might only want to indicate an invoice is sent:<br><br>IF(Dimensionality()=3, "Invoiced"). | -      |

### Exists

**Exists()** determines whether a specific field value has already been loaded into the field in the load script. The function returns TRUE or FALSE, so can be used in the **where** clause of a **LOAD** statement or an **IF** function.

You can also use **Not Exists()** to determine if a field value has not been loaded, but caution is recommended if you use **Not Exists()** in a where clause. The **Exists()** function tests both previously loaded tables and previously loaded values in the current table. So, only the first occurrence will be loaded. When the second occurrence is encountered, the value is already loaded. See the examples for more information.

### Syntax:

```
Exists(field_name [, expr])
```

**Return data type:** Boolean

### Arguments:

#### Exists arguments

| Argument   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| field_name | <p>The name of the field where you want to search for a value. You can use an explicit field name without quotes.</p> <p>The field must already be loaded by the script. That means, you cannot refer to a field that is loaded in a clause further down in the script.</p>                                                                                                                                                                                                                                                   |
| expr       | <p>The value that you want to check if it exists. You can use an explicit value or an expression that refers to one or several fields in the current load statement.</p> <div data-bbox="395 1160 1385 1243" style="border: 1px solid gray; padding: 5px; margin: 10px 0;">  You cannot refer to fields that are not included in the current load statement.         </div> <p>This argument is optional. If you omit it, the function will check if the value of <b>field_name</b> in the current record already exists.</p> |

### Example 1:

```
Exists (Employee)
```

Returns -1 (True) if the value of the field **Employee** in the current record already exists in any previously read record containing that field.

### Example 2:

```
Exists(Employee, 'Bill')
```

Returns -1 (True) if the field value **'Bill'** is found in the current content of the field **Employee**.

The statements `Exists (Employee, Employee)` and `Exists (Employee)` are equivalent.

### Example 3:

```
Employees:
LOAD * inline [
```

```
Employee|ID|Salary
Bill|001|20000
John|002|30000
Steve|003|35000
] (delimiter is '|');
```

```
Citizens:
Load * inline [
Employee|Address
Bill|New York
Mary|London
Steve|Chicago
Lucy|Madrid
Lucy|Paris
John|Miami
] (delimiter is '|') where Exists (Employee);
```

```
Drop Tables Employees;
```

This results in a table called Citizens in the data model, which can be viewed as a table chart using the dimensions Employee and Address.

The where clause: where Exists (Employee), means only the names from the table Citizens that are also in Employees are loaded into the new table. The Drop statement removes the temporary table Employees to avoid confusion.

Example 3 results

| Employee | Address  |
|----------|----------|
| Bill     | New York |
| John     | Miami    |
| Steve    | Chicago  |

### Example 4:

```
Employees:
Load * inline [
Employee|ID|Salary
Bill|001|20000
John|002|30000
Steve|003|35000
] (delimiter is '|');
```

```
Citizens:
Load * inline [
Employee|Address
Bill|New York
Mary|London
Steve|Chicago
Lucy|Madrid
Lucy|Paris
John|Miami
```

## 9 Script syntax and chart functions

---

```
] (delimiter is '|') where not Exists (Employee);
```

```
Drop Tables Employees;
```

The where clause includes not: where not Exists (Employee).

This means that only the names from the table Citizens that are not in Employees are loaded into the new table.

Note that there are two values for Lucy in the Citizens table, but only one is included in the result table. When you load the first row with the value Lucy, it is included in the Employee field. Hence, when the second line is checked, the value already exists.

Example 4 results

| Employee | Address |
|----------|---------|
| Mary     | London  |
| Lucy     | Madrid  |

### Example 5:

This example shows how to load all values.

```
Employees:
Load Employee AS Name;
LOAD * inline [
Employee|ID|Salary
Bill|001|20000
John|002|30000
Steve|003|35000
] (delimiter is '|');
```

```
Citizens:
Load * inline [
Employee|Address
Bill|New York
Mary|London
Steve|Chicago
Lucy|Madrid
Lucy|Paris
John|Miami
] (delimiter is '|') where not Exists (Name, Employee);
```

```
Drop Tables Employees;
```

To be able to get all values for Lucy, two things were changed:

- A preceding load to the Employees table was inserted where Employee was renamed to Name.  
Load Employee AS Name;

- The Where condition in Citizens was changed to:  
not Exists (Name, Employee).

This creates fields for Name and Employee. When the second row with Lucy is checked, it still does not exist in Name.

Example 5 results

| Employee | Address |
|----------|---------|
| Mary     | London  |
| Lucy     | Madrid  |
| Lucy     | Paris   |

Data used in example:

```
LOAD * inline [
Employee|ID|Salary
Bill|001|20000
John|002|30000
Steve|003|35000
] (delimiter is '|');
```

```
Citizens:
Load * inline [
Employee|Address
Bill|New York
Mary|London
Steve|Chicago
Lucy|Madrid
Lucy|Paris
John|Miami
] (delimiter is '|');
```

### FieldIndex

**FieldIndex()** returns the position of the field value **value** in the field **field\_name** (by load order).

#### Syntax:

```
FieldIndex(field_name , value)
```

**Return data type:** integer

#### Arguments:

- **field\_name:** Name of the field for which the index is required. For example, the column in a table. Must be given as a string value. This means that the field name must be enclosed by single quotes.
- **value:** The value of the field **field\_name**.

### Limitations:

- Sorting on y-values in charts or sorting by expression columns in tables is not allowed when this chart function is used in any of the chart's expressions. These sort alternatives are therefore automatically disabled. When you use this chart function in a visualization or table, the sorting of the visualization will revert back to the sorted input to this function. This limitation does not apply to the equivalent script function.
- If **value** cannot be found among the field values of the field **field\_name**, 0 is returned.

### Examples:

Add the example data below to your document and run it. The following examples use the field: **First name** from the table**Names**.

Examples and results

| Example                                                                                                                                                                       | Result                                                                                                                                                                                                                            |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Chart function - in a table containing the dimension <b>First name</b> , add as a measure:<br><br><pre>FieldIndex ('First name', 'John')</pre>                                | 1, because 'John' appears first in the load order of the <b>First name</b> field. Note that in a list box <b>John</b> would appear as number 2 from the top as it's sorted alphabetically and not as in the load order.           |
| Chart function with <b>First name</b> :<br><br><pre>FieldIndex ('First name', 'Peter')</pre>                                                                                  | 4, because <b>FieldIndex()</b> returns only one value, that is the first occurrence in the load order.                                                                                                                            |
| Script function - given the table <b>Names</b> is loaded, as in the example data:<br><br><pre>John1: Load FieldIndex('First name', 'John') as MyJohnPos Resident Names;</pre> | MyJohnPos=1, because 'John' appears first in the load order of the <b>First name</b> field. Note that in a list box <b>John</b> would appear as number 2 from the top as it's sorted alphabetically and not as in the load order. |
| Script function with <b>Names</b> :<br><br><pre>Peter1: Load FieldIndex('First name', 'Peter') as MyPeterPos Resident Names;</pre>                                            | MyPeterPos=4, because <b>FieldIndex()</b> returns only one value, that is the first occurrence in the load order.                                                                                                                 |

### Data used in example:

```
Names:
LOAD * inline [
```

```
"First name"|"Last name"|Initials|"Has cellphone"
John|Anderson|JA|Yes
Sue|Brown|SB|Yes
Mark|Carr|MC |No
Peter|Devonshire|PD|No
Jane|Elliot|JE|Yes
Peter|Franc|PF|Yes] (delimiter is '|');
```

```
John1:
Load FieldIndex('First name','John') as MyJohnPos
Resident Names;
```

```
Peter1:
Load FieldIndex('First name','Peter') as MyPeterPos
Resident Names;
```

### FieldValue

**FieldValue()** returns the value found in position **elem\_no** of the field **field\_name** (by load order).

#### Syntax:

```
FieldValue(field_name , elem_no)
```

**Return data type:** dual

#### Arguments:

- **field\_name:** Name of the field for which the index is required. For example, the column in a table. Must be given as a string value. This means that the field name must be enclosed by single quotes.
- **elem\_no:** The position (element) number of the field, following the load order, that the value is returned for. This could correspond to the row in a table, but it depends on the order in which the elements (rows) are loaded.

#### Limitations:

- Sorting on y-values in charts or sorting by expression columns in tables is not allowed when this chart function is used in any of the chart's expressions. These sort alternatives are therefore automatically disabled. When you use this chart function in a visualization or table, the sorting of the visualization will revert back to the sorted input to this function. This limitation does not apply to the equivalent script function.
- If **elem\_no** is larger than the number of field values, NULL is returned.

#### Examples:

Add the example data below to your document and run it. The following examples use the field: **First name** from the table**Names**.

### Examples and results

| Example                                                                                                                                                               | Result                                                                                                                                                                                                                                              |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>Chart function - in a table containing the dimension <b>First name</b>, add as a measure:</p> <pre>FieldValue('First name', '1')</pre>                             | <p>John, because John appears first in the load order of the <b>First name</b> field. Note that in a list box <b>John</b> would appear as number 2 from the top, after <b>Jane</b>, as it's sorted alphabetically and not as in the load order.</p> |
| <p>Chart function with <b>First name</b>:</p> <pre>FieldValue('First name', '7')</pre>                                                                                | <p>NULL, because there are only 6 values in the <b>First name</b> field.</p>                                                                                                                                                                        |
| <p>Script function - given the table <b>Names</b> is loaded, as in the example data:</p> <pre>John1: Load FieldValue('First name', 1) as MyPos1 Resident Names;</pre> | <p>MyPos1=John, because 'John' appears first in the load order of the <b>First name</b> field.</p>                                                                                                                                                  |
| <p>Script function with <b>Names</b>:</p> <pre>Peter1: Load FieldValue('First name', 7) as MyPos2 Resident Names;</pre>                                               | <p>MyPo2s= - (Null), because there are only 6 values in the <b>First name</b> field.</p>                                                                                                                                                            |

Data used in example:

```
Names:
LOAD * inline [
"First name"|"Last name"|"Initials"|"Has cellphone"
John|Anderson|JA|Yes
Sue|Brown|SB|Yes
Mark|Carr|MC |No
Peter|Devonshire|PD|No
Jane|Elliot|JE|Yes
Peter|Franc|PF|Yes] (delimiter is '|');
John1:
Load FieldValue('First name', 1) as MyPos1
Resident Names;

Peter1:
Load FieldValue('First name', 7) as MyPos2
Resident Names;
```

### FieldValueCount

**FieldValueCount()** is an **integer** function that finds the number of distinct values in a field.

### Syntax:

```
FieldValueCount(field_name)
```

**Return data type:** integer

### Arguments:

- `field_name`: Name of the field for which the index is required. For example, the column in a table. Must be given as a string value. This means that the field name must be enclosed by single quotes.

*Sorting on y-values in charts or sorting by expression columns in tables is not allowed when this chart function is used in any of the chart's expressions. These sort alternatives are therefore automatically disabled. When you use this chart function in a visualization or table, the sorting of the visualization will revert back to the sorted input to this function.*

### Examples:

Add the example data below to your document and run it. The following examples use the field: **First name** from the table**Names**.

#### Examples and results

| Example                                                                                                                                                                                  | Result                                                                      |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------|
| Chart function - in a table containing the dimension <b>First name</b> , add as a measure:<br><br><code>FieldValueCount('First name')</code>                                             | 5 as <b>Peter</b> appears twice.                                            |
| Chart function with <b>First name</b> :<br><br><code>FieldValueCount('Initials')</code>                                                                                                  | 6 as <b>Initials</b> only has distinct values.                              |
| Script function - given the table <b>Names</b> is loaded, as in the example data:<br><br><code>John1:<br/>Load FieldValueCount('First name') as MyFieldCount1<br/>Resident Names;</code> | <code>MyFieldCount1=5</code> , because 'John' appears twice.                |
| Script function with <b>Names</b> :<br><br><code>John1:<br/>Load FieldValueCount('Initials') as MyInitialsCount1<br/>Resident Names;</code>                                              | <code>MyFieldCount1=6</code> , because 'Initials' only has distinct values. |

Data used in example:

### Data used in example:

```
Names:
LOAD * inline [
"First name"|"Last name"|"Initials"|"Has cellphone"
```

```
John|Anderson|JA|Yes
Sue|Brown|SB|Yes
Mark|Carr|MC |No
Peter|Devonshire|PD|No
Jane|Elliot|JE|Yes
Peter|Franc|PF|Yes] (delimiter is '|');
```

```
FieldCount1:
Load FieldValueCount('First name') as MyFieldCount1
Resident Names;
```

```
FieldCount2:
Load FieldValueCount('Initials') as MyInitialsCount1
Resident Names;
```

### LookUp

**LookUp()** looks into a table that is already loaded and returns the value of **field\_name** corresponding to the first occurrence of the value **match\_field\_value** in the field **match\_field\_name**. The table can be the current table or another table previously loaded.

#### Syntax:

```
lookup(field_name, match_field_name, match_field_value [, table_name])
```

**Return data type:** dual

#### Arguments:

LookUp arguments

| Argument          | Description                                                                                                                                                                                |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| field_name        | Name of the field for which the return value is required. Input value must be given as a string (for example, quoted literals).                                                            |
| match_field_name  | Name of the field to look up <b>match_field_value</b> in. Input value must be given as a string (for example, quoted literals).                                                            |
| match_field_value | Value to look up in <b>match_field_name</b> field.                                                                                                                                         |
| table_name        | Name of the table in which to look up the value. Input value must be given as a string (for example quoted literals).<br><br>If <b>table_name</b> is omitted the current table is assumed. |

*Arguments without quotes refer to the current table. To refer to other tables, enclose an argument in single quotes.*

### Limitations:

The order in which the search is made is the load order, unless the table is the result of complex operations such as joins, in which case, the order is not well defined. Both **field\_name** and **match\_field\_name** must be fields in the same table, specified by **table\_name**.

If no match is found, NULL is returned.

### Example:

The sample data uses the **Lookup()** function in the following form:

```
Lookup('Category', 'ProductID', ProductID, 'ProductList')
```

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
ProductList:
Load * Inline [
ProductID|Product|Category|Price
1|AA|1|1
2|BB|1|3
3|CC|2|8
4|DD|3|2
] (delimiter is '|');

OrderData:
Load *, Lookup('Category', 'ProductID', ProductID, 'ProductList') as CategoryID
Inline [
InvoiceID|CustomerID|ProductID|Units
1|Astrida|1|8
1|Astrida|2|6
2|Betacab|3|10
3|Divadip|3|5
4|Divadip|4|10
] (delimiter is '|');

Drop Table ProductList
```

The **ProductList** table is loaded first.

The **Lookup()** function is used to build the **OrderData** table. It specifies the third argument as **ProductID**. This is the field for which the value is to be looked up in the second argument '**ProductID**' in the **ProductList**, as denoted by the enclosing single quotes.

The function returns the value for '**Category**' (in the **ProductList** table), loaded as **CategoryID**.

The **drop** statement deletes the **ProductList** table from the data model, because it is not required, which leaves the **OrderData** table with the following result:

Example 1 results

| ProductID | InvoiceID | CustomerID | Units | CategoryID |
|-----------|-----------|------------|-------|------------|
|-----------|-----------|------------|-------|------------|

|   |   |         |    |   |
|---|---|---------|----|---|
| 1 | 1 | Astrida | 8  | 1 |
| 2 | 1 | Astrida | 6  | 1 |
| 3 | 2 | Betacab | 10 | 2 |
| 3 | 3 | Divadip | 5  | 2 |
| 4 | 4 | Divadip | 10 | 3 |

*The Lookup() function is flexible and can access any previously loaded table. However, it is slow compared with the Applymap() function.*

### NoOfRows

**NoOfRows()** returns the number of rows in the current column segment in a table. For bitmap charts, **NoOfRows()** returns the number of rows in the chart's straight table equivalent.

*Sorting on y-values in charts or sorting by expression columns in tables is not allowed when this chart function is used in any of the chart's expressions. These sort alternatives are therefore automatically disabled. When you use this chart function in a visualization or table, the sorting of the visualization will revert back to the sorted input to this function.*

If the table or table equivalent has multiple vertical dimensions, the current column segment will include only rows with the same values as the current row in all dimension columns, except for the column showing the last dimension in the inter-field sort order.

#### Syntax:

```
NoOfRows ([TOTAL])
```

**Return data type:** integer

#### Arguments:

- **TOTAL:** If the table is one-dimensional or if the qualifier **TOTAL** is used as argument, the current column segment is always equal to the entire column.

#### Example:

```
if(RowNo()= NoOfRows(), 0, Above(sum(Sales)))
```

### Peek

**Peek()** finds the value of a field in a table for a row that has already been loaded or that exists in internal memory. The row number can be specified, as can the table.

#### Syntax:

```
Peek(field_name[, row_no[, table_name]])
```

**Return data type:** dual

**Arguments:**

Peek arguments

| Argument   | Description                                                                                                                                                                                                                                                                                                      |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| field_name | Name of the field for which the return value is required. Input value must be given as a string (for example, quoted literals).                                                                                                                                                                                  |
| row_no     | The row in the table that specifies the field required. Can be an expression, but must resolve to an integer. 0 denotes the first record, 1 the second, and so on. Negative numbers indicate order from the end of the table. -1 denotes the last record read.<br><br>If no <b>row</b> is stated, -1 is assumed. |
| table_name | A table label without the ending colon. If no <b>table_name</b> is stated, the current table is assumed. If used outside the <b>LOAD</b> statement or referring to another table, the <b>table_name</b> must be included.                                                                                        |

**Limitations:**

In the first record of an internal table, the function returns NULL.

**Example 1:**

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
EmployeeDates:
Load * Inline [
EmployeeCode|StartDate|EndDate
101|02/11/2010|23/06/2012
102|01/11/2011|30/11/2013
103|02/01/2012|
104|02/01/2012|31/03/2012
105|01/04/2012|31/01/2013
106|02/11/2013|
] (delimiter is '|');

FirstEmployee:
Load EmployeeCode, Peek('EmployeeCode',0) As EmpCode
Resident EmployeeDates;
```

EmpCode = 101, because Peek(EmployeeCode,0) returns the first value of EmployeeCode in the table EmployeeDates.

Substituting the value of the argument **row\_no** returns the values of other rows in the table, as follows:

Peek('EmployeeCode',2) returns the third value in the table: 103.

---

## 9 Script syntax and chart functions

---

However, note that without specifying the table as the third argument **table\_no**, the function references the current (in this case, internal) table. The result of `peek(EmployeeCode,-2)` is multiple values:

Example 1 results

| EmployeeCode | EmpCode |
|--------------|---------|
| 101          | -       |
| 102          | -       |
| 103          | 101     |
| 104          | 102     |
| 105          | 103     |
| 106          | 104     |

### Example 2:

```
FirstEmployee:
Load EmployeeCode, Peek('EmployeeCode',-2,'EmployeeDates') AS EmpCode
Resident EmployeeDates;
```

By specifying the argument **table\_no** as 'EmployeeDates', the function returns the second-to-last value of EmployeeCode in the table EmployeeDates: 105.

### Example 3:

The **Peek()** function can be used to reference data that is not yet loaded.

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
T1:
LOAD * inline [
ID, value
1|3
1|4
1|6
3|7
3|8
2|1
2|11
5|2
5|78
5|13
] (delimiter is '|');
T2:
LOAD
*,
IF(ID=Peek('ID'), Peek('List')&','&value,value) AS List
RESIDENT T1
ORDER BY ID ASC;
DROP TABLE T1;
```

Create a table in a sheet in your document with **ID**, **List**, and **Value** as the dimensions.

Example 3 results

| ID | List    | Value |
|----|---------|-------|
| 1  | 6       | 6     |
| 1  | 6,3     | 3     |
| 1  | 6,3,4   | 4     |
| 2  | 11      | 11    |
| 2  | 11,10   | 10    |
| 2  | 11,10,1 | 1     |
| 3  | 8       | 8     |
| 3  | 8,7     | 7     |
| 5  | 13      | 13    |
| 5  | 13,2    | 2     |
| 5  | 13,2,78 | 78    |

The **IF()** statement is built from the temporary table T1.

`Peek('ID')` references the field ID in the previous row in the current table T2.

`Peek('List')` references the field List in the previous row in the table T2, currently being built as the expression is evaluated.

The statement is evaluated as follows:

If the current value of ID is the same as the previous value of ID, then write the value of `Peek('List')` concatenated with the current value of Value. Otherwise, write the current value of Value only.

If `Peek('List')` already contains a concatenated result, the new result of `Peek('List')` will be concatenated to it.

*Note the **Order by** clause. This specifies how the table is ordered (by ID in ascending order). Without this, the `Peek()` function will use whatever arbitrary ordering the internal table has, which can lead to unpredictable results.*

### Previous

**Previous()** finds the value of the **expr** expression using data from the previous input record. In the first record of an internal table, the function will return NULL.

#### Syntax:

```
Previous(expr)
```

**Return data type:** dual

**Arguments:**

Previous arguments

| Argument | Description                                                                                                                                                                                                                                                                                                                                                                        |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| expr     | The expression or field containing the data to be measured.<br>The expression can contain nested <b>previous()</b> functions in order to access records further back. Data are fetched directly from the input source, making it possible to refer also to fields that have not been loaded into QlikView, that is, even if they have not been stored in its associative database. |

**Limitations:**

In the first record of an internal table, the function returns NULL.

**Example 1:**

```
sales2013:
Load *, (Sales - Previous(Sales))as Increase Inline [
Month|Sales
1|12
2|13
3|15
4|17
5|21
6|21
7|22
8|23
9|32
10|35
11|40
12|41
] (delimiter is '|');
```

By using the **Previous()** function in the **Load** statement, we can compare the current value of Sales with the preceding value, and use it in a third field, Increase.

Example 1 results

| Month | Sales | Increase |
|-------|-------|----------|
| 1     | 12    | -        |
| 2     | 13    | 1        |
| 3     | 15    | 2        |
| 4     | 17    | 2        |
| 5     | 21    | 4        |
| 6     | 21    | 0        |

## 9 Script syntax and chart functions

---

| Month | Sales | Increase |
|-------|-------|----------|
| 7     | 22    | 1        |
| 8     | 23    | 1        |
| 9     | 32    | 9        |
| 10    | 35    | 3        |
| 11    | 40    | 5        |
| 12    | 41    | 1        |

### Example 2:

Sales2013:

```
Load * Inline [
```

```
Month|Sales
```

```
1|12
```

```
2|13
```

```
3|15
```

```
4|17
```

```
5|21
```

```
6|21
```

```
7|22
```

```
8|23
```

```
9|32
```

```
10|35
```

```
11|40
```

```
12|41
```

```
] (delimiter is '|');
```

Sales:

```
NoConcatenate Load *, (Sales - Previous(Sales))as Increase Resident Sales2013 where Month > 6;
```

```
Drop Table Sales2013;
```

In this example we exclude the records where Month is 6 or less by using a **WHERE** clause. This still makes it possible to use **Previous()** as the function can refer to data that is excluded from the load.

In this case the calculation of Increase for Month=7 refers to the Sales value for Month=6, which is excluded from the load.

Example 2 results

| Month | Sales | Increase |
|-------|-------|----------|
| 7     | 22    | 1        |
| 8     | 23    | 1        |
| 9     | 32    | 9        |
| 10    | 35    | 3        |

| Month | Sales | Increase |
|-------|-------|----------|
| 11    | 40    | 5        |
| 12    | 41    | 1        |

### Top

**Top()** evaluates an expression at the first (top) row of a column segment in a table. The row for which it is calculated depends on the value of **offset**, if present, the default being the top row. For charts other than tables, the **Top()** evaluation is made on the first row of the current column in the chart's straight table equivalent.

#### Syntax:

```
Top ([TOTAL] expr [, offset [, count]])
```

**Return data type:** dual

#### Arguments:

- **expr:** The expression or field containing the data to be measured.
- **offset:** Specifying an **offset n**, greater than 0, moves the evaluation of the expression **n** rows further up from the current row. Specifying an offset of 0 will evaluate the expression on the current row. Specifying a negative offset number makes the **Above** function work like the **Below** function with the corresponding positive offset number.
- **count:** By specifying a third argument **count** greater than 1, the function will return a range of **count** values, one for each of **count** table rows counting upwards from the original cell. In this form, the function can be used as an argument to any of the special range functions. *Range functions (page 1477)*
- **TOTAL:** If the table is one-dimensional or if the qualifier **TOTAL** is used as argument, the current column segment is always equal to the entire column.

*A column segment is defined as a consecutive subset of cells having the same values for the dimensions in the current sort order. Inter-record chart functions are computed in the column segment excluding the right-most dimension in the equivalent straight table chart. If there is only one dimension in the chart, or if the TOTAL qualifier is specified, the expression evaluates across full table.*

*If the table or table equivalent has multiple vertical dimensions, the current column segment will include only rows with the same values as the current row in all dimension columns, except for the column showing the last dimension in the inter-field sort order.*

### Limitations:

- Sorting on y-values in charts or sorting by expression columns in tables is not allowed when this chart function is used in any of the chart's expressions. These sort alternatives are therefore automatically disabled. When you use this chart function in a visualization or table, the sorting of the visualization will revert back to the sorted input to this function.
- Recursive calls will return NULL.

### Examples and results:

#### Example 1:

Example table output

| Customer   | Sum(Sales) | Top(Sum(Sales)) | Sum(Sales) + Top(Sum(Sales)) | Top offset 3 |
|------------|------------|-----------------|------------------------------|--------------|
|            | 2566       | 587             | 3153                         | 3249         |
| Astrida    | 587        | 587             | 1174                         | 1270         |
| Betacab    | 539        | 587             | 1126                         | 1222         |
| Canutility | 683        | 587             | 1270                         | 1366         |
| Divadip    | 757        | 587             | 1344                         | 1440         |

In the representation of the table chart shown in this example, the table is created from the dimension **Customer** and the measures: `sum(Sales)` and `Top(Sum(Sales))`.

The column **Top(Sum(Sales))** returns 587 for the all rows because this is the value of the top row: **Astrida**.

The table also shows more complex measures: one created from `sum(Sales)+Top(Sum(Sales))` and one labeled **Top offset 3**, which is created using the expression `sum(Sales)+Top(Sum(Sales), 3)` and has the argument **offset** set to 3. It adds the **Sum(Sales)** value for the current row to the value from the third row from the top row, that is, the current row plus the value for **Canutility**.

#### Example 2:

In the representations of table charts shown in this example, more dimensions have been added to the charts: **Month** and **Product**. For charts with more than one dimension, the results of expressions containing the **Above**, **Below**, **Top**, and **Bottom** functions depend on the order in which the column dimensions are sorted by QlikView. QlikView evaluates the functions based on the column segments that result from the dimension that is sorted last. The column sort order is controlled under **Sort** and is not necessarily the order in which the columns appear in a table. (Some rows are not shown, to save space.)

Example first table output

| Customer | Product | Month | Sum(Sales) | First value |
|----------|---------|-------|------------|-------------|
|          |         |       | 2566       | -           |

## 9 Script syntax and chart functions

| Customer | Product | Month | Sum(Sales) | First value |
|----------|---------|-------|------------|-------------|
| Astrida  | AA      | Jan   | 46         | 46          |
| Astrida  | AA      | Feb   | 60         | 46          |
| Astrida  | AA      | Mar   | 70         | 46          |
| ...      | ...     | ...   | ...        | ...         |
| Astrida  | AA      | Sep   | 78         | 46          |
| Astrida  | AA      | Oct   | 12         | 46          |
| Astrida  | AA      | Nov   | 78         | 46          |
| Astrida  | AA      | Dec   | 22         | 46          |
| Astrida  | BB      | Jan   | 46         | 46          |

Example second table output

| Customer | Product | Month | Sum(Sales)  | First value |
|----------|---------|-------|-------------|-------------|
|          |         |       | <b>2566</b> | -           |
| Astrida  | AA      | Jan   | 46          | 46          |
| Astrida  | BB      | Jan   | 46          | 46          |
| Astrida  | AA      | Feb   | 60          | 60          |
| Astrida  | BB      | Feb   | 60          | 60          |
| Astrida  | AA      | Mar   | 70          | 70          |
| Astrida  | BB      | Mar   | 70          | 70          |
| Astrida  | AA      | Apr   | 13          | 13          |
| Astrida  | BB      | Apr   | 13          | 13          |

Please refer to Example 2 in the **Above** function for further details.

### Example 3:

The **Top** function can be used as input to the range functions. For example: `RangeAvg (Top(Sum(Sales), 1, 3))`.

In the arguments for the **Top()** function, offset is set to 1 and count is set to 3. The function finds the results of the expression **Sum(Sales)** on the three rows starting with the row below the bottom row in the column segment (because the offset=1), and the two rows below that (where there is a row). These three values are used as input to the `RangeAvg()` function, which finds the average of the values in the supplied range of numbers.

A table with **Customer** as dimension gives the following results for the `RangeAvg()` expression.

Example table output

| Customer   | RangeAvg (Top(Sum(Sales),1,3)) |
|------------|--------------------------------|
| Astrida    | 603                            |
| Betacab    | 603                            |
| Canutility | 603                            |
| Divadip    | 603                            |

### Data used in examples:

Monthnames:

```
LOAD * INLINE [
Month, Monthnumber
Jan, 1
Feb, 2
Mar, 3
Apr, 4
May, 5
Jun, 6
Jul, 7
Aug, 8
Sep, 9
Oct, 10
Nov, 11
Dec, 12
];
```

Sales2013:

```
crosstable (Month, Sales) LOAD * inline [
Customer|Jan|Feb|Mar|Apr|May|Jun|Jul|Aug|Sep|Oct|Nov|Dec
Astrida|46|60|70|13|78|20|45|65|78|12|78|22
Betacab|65|56|22|79|12|56|45|24|32|78|55|15
Canutility|77|68|34|91|24|68|57|36|44|90|67|27
Divadip|57|36|44|90|67|27|57|68|47|90|80|94
] (delimiter is '|');
```

To get the months to sort in the correct order, when you create your charts, go to the **Sort** tab of the chart properties, and mark the checkbox **Expression** under **Sort by**. In the expression box write `Monthnumber`.

### Secondarydimensionality

**SecondaryDimensionality()** returns the number of dimension pivot table rows that have non-aggregation content, that is, do not contain partial sums or collapsed aggregates. This function is the equivalent of the **dimensionality()** function for horizontal pivot table dimensions.

*Sorting on y-values in charts or sorting by expression columns in tables is not allowed when this chart function is used in any of the chart's expressions. These sort alternatives are therefore automatically disabled. When you use this chart function in a visualization or table, the sorting of the visualization will revert back to the sorted input to this function.*

### Syntax:

**SecondaryDimensionality** ( )

**Return data type:** integer

The **secondarydimensionality** function always returns 0 when used outside of pivot tables.

### After

**After()** returns the value of an expression evaluated with a pivot table's dimension values as they appear in the column after the current column within a row segment in the pivot table.

### Syntax:

```
after([total] expression [, offset [,n]])
```

*This function returns NULL in all chart types except pivot tables.*

*Sorting on y-values in charts or sorting by expression columns in tables is not allowed when this chart function is used in any of the chart's expressions. These sort alternatives are therefore automatically disabled. When you use this chart function in a visualization or table, the sorting of the visualization will revert back to the sorted input to this function.*

### Arguments:

- **expression:** The expression or field containing the data to be measured.
- **offset:** Specifying an **offset n**, greater than 0, moves the evaluation of the expression **n** rows further up from the current row. Specifying an offset of 0 will evaluate the expression on the current row. Specifying a negative offset number makes the **Above** function work like the **Below** function with the corresponding positive offset number.
- **n:** By specifying a third parameter **n** greater than 1, the function will return a range of **n** values, one for each of **n** table rows counting to the right from the original cell.
- **TOTAL:** If the table is one-dimensional or if the qualifier **TOTAL** is used as argument, the current column segment is always equal to the entire column.

On the last column of a row segment a NULL value will be returned, as there is no column after this one.

If the pivot table has multiple horizontal dimensions, the current row segment will include only columns with the same values as the current column in all dimension rows except for the row showing the last horizontal dimension of the inter-field sort order. The inter-field sort order for horizontal dimensions in pivot tables is defined simply by the order of the dimensions from top to bottom.

### Example:

```
after(sum(Sales))
```

```
after(sum(Sales), 2)
```

```
after(total sum(Sales))
```

`rangeavg (after(sum(x),1,3))` returns an average of the three results of the **sum(x)** function evaluated in the three columns immediately to the right of the current column.

### Before

**Before()** returns the value of an expression evaluated with a pivot table's dimension values as they appear in the column before the current column within a row segment in the pivot table.

#### Syntax:

```
before([total] expression [, offset [,n]])
```

*This function returns NULL in all chart types except pivot tables.*

*Sorting on y-values in charts or sorting by expression columns in tables is not allowed when this chart function is used in any of the chart's expressions. These sort alternatives are therefore automatically disabled. When you use this chart function in a visualization or table, the sorting of the visualization will revert back to the sorted input to this function.*

#### Arguments:

- **expression**: The expression or field containing the data to be measured.
- **offset**: Specifying an **offset n**, greater than 0, moves the evaluation of the expression **n** rows further up from the current row. Specifying an offset of 0 will evaluate the expression on the current row. Specifying a negative offset number makes the **Above** function work like the **Below** function with the corresponding positive offset number.
- **n**: By specifying a third parameter **n** greater than 1, the function will return a range of **n** values, one for each of **n** table rows counting to the right from the original cell.
- **TOTAL**: If the table is one-dimensional or if the qualifier **TOTAL** is used as argument, the current column segment is always equal to the entire column.

On the first column of a row segment a NULL value will be returned, as there is no column before this one.

If the pivot table has multiple horizontal dimensions, the current row segment will include only columns with the same values as the current column in all dimension rows except for the row showing the last horizontal dimension of the inter-field sort order. The inter-field sort order for horizontal dimensions in pivot tables is defined simply by the order of the dimensions from top to bottom.

#### Examples:

```
before(sum(Sales))
```

```
before(sum(Sales), 2)
```

```
before(total sum(Sales))
```

`rangeavg (before(sum(x),1,3))` returns an average of the three results of the **sum(x)** function evaluated in the three columns immediately to the left of the current column.

### First

**First()** returns the value of an expression evaluated with a pivot table's dimension values as they appear in the first column of the current row segment in the pivot table. This function returns NULL in all chart types except pivot tables.

### Syntax:

```
first([total] expression [, offset [,n]])
```

### Arguments:

- **expression**: The expression or field containing the data to be measured.
- **offset**: Specifying an **offset n**, greater than 0, moves the evaluation of the expression **n** rows further up from the current row. Specifying an offset of 0 will evaluate the expression on the current row. Specifying a negative offset number makes the **Above** function work like the **Below** function with the corresponding positive offset number.
- **n**: By specifying a third parameter **n** greater than 1, the function will return a range of **n** values, one for each of **n** table rows counting to the right from the original cell.
- **TOTAL**: If the table is one-dimensional or if the qualifier **TOTAL** is used as argument, the current column segment is always equal to the entire column.

*Sorting on y-values in charts or sorting by expression columns in tables is not allowed when this chart function is used in any of the chart's expressions. These sort alternatives are therefore automatically disabled. When you use this chart function in a visualization or table, the sorting of the visualization will revert back to the sorted input to this function.*

If the pivot table has multiple horizontal dimensions, the current row segment will include only columns with the same values as the current column in all dimension rows except for the row showing the last horizontal dimension of the inter-field sort order. The inter-field sort order for horizontal dimensions in pivot tables is defined simply by the order of the dimensions from top to bottom.

### Examples:

```
first(sum(Sales))
```

```
first(sum(Sales), 2)
```

```
first(total sum(Sales)
```

```
rangeavg (first(sum(x) , 1, 5))
```

 returns an average of the results of the **sum(x)** function evaluated on the five leftmost columns of the current row segment.

### Last

**Last()** returns the value of an expression evaluated with a pivot table's dimension values as they appear in the last column of the current row segment in the pivot table. This function returns NULL in all chart types except pivot tables.

### Syntax:

```
last([total] expression [, offset [,n]])
```

### Arguments:

- **expression**: The expression or field containing the data to be measured.
- **offset**: Specifying an **offset n**, greater than 0, moves the evaluation of the expression **n** rows further up from the current row. Specifying an offset of 0 will evaluate the expression on the current row. Specifying a negative offset number makes the **Above** function work like the **Below** function with the corresponding positive offset number.
- **n**: By specifying a third parameter **n** greater than 1, the function will return a range of **n** values, one for each of **n** table rows counting to the right from the original cell.
- **TOTAL**: If the table is one-dimensional or if the qualifier **TOTAL** is used as argument, the current column segment is always equal to the entire column.

If the pivot table has multiple horizontal dimensions, the current row segment will include only columns with the same values as the current column in all dimension rows except for the row showing the last horizontal dimension of the inter-field sort order. The inter-field sort order for horizontal dimensions in pivot tables is defined simply by the order of the dimensions from top to bottom.

*Sorting on y-values in charts or sorting by expression columns in tables is not allowed when this chart function is used in any of the chart's expressions. These sort alternatives are therefore automatically disabled. When you use this chart function in a visualization or table, the sorting of the visualization will revert back to the sorted input to this function.*

### Example:

```
last(sum(Sales))
```

```
last(sum(Sales), 2)
```

```
last(total sum(Sales)
```

`rangeavg (last(sum(x),1,5))` returns an average of the results of the **sum(x)** function evaluated on the five rightmost columns of the current row segment.

## ColumnNo

**ColumnNo()** returns the number of the current column within the current row segment in a pivot table. The first column is number 1.

### Syntax:

```
ColumnNo ([total])
```

### Arguments:

- **TOTAL**: If the table is one-dimensional or if the qualifier **TOTAL** is used as argument, the current column segment is always equal to the entire column.

If the pivot table has multiple horizontal dimensions, the current row segment will include only columns with the same values as the current column in all dimension rows except for the row showing the last horizontal dimension of the inter-field sort order. The inter-field sort order for horizontal dimensions in pivot tables is defined simply by the order of the dimensions from top to bottom.

*Sorting on y-values in charts or sorting by expression columns in tables is not allowed when this chart function is used in any of the chart's expressions. These sort alternatives are therefore automatically disabled. When you use this chart function in a visualization or table, the sorting of the visualization will revert back to the sorted input to this function.*

### Example:

```
if(ColumnNo()=1, 0, sum(Sales) / before(sum(Sales)))
```

## NoOfColumns

**NoOfColumns()** returns the number of columns in the current row segment in a pivot table.

### Syntax:

```
NoOfColumns ([total])
```

### Arguments:

- **TOTAL:** If the table is one-dimensional or if the qualifier **TOTAL** is used as argument, the current column segment is always equal to the entire column.

If the pivot table has multiple horizontal dimensions, the current row segment will include only columns with the same values as the current column in all dimension rows except for the row showing the last dimension in the inter-field sort order. The inter-field sort order for horizontal dimensions in pivot tables is defined simply by the order of the dimensions from top to bottom.

*Sorting on y-values in charts or sorting by expression columns in tables is not allowed when this chart function is used in any of the chart's expressions. These sort alternatives are therefore automatically disabled. When you use this chart function in a visualization or table, the sorting of the visualization will revert back to the sorted input to this function.*

### Example:

```
if(ColumnNo()=NoofColumns(), 0, after(sum(Sales)))
```

## Logical functions

This section describes functions handling logical operations. All functions can be used in both the load script and in chart expressions.

### IsNum

Returns -1 (True) if the expression can be interpreted as a number, otherwise 0 (False).

```
IsNum(expr)
```

### IsText

Returns -1 (True) if the expression has a text representation, otherwise 0 (False).

```
IsText (expr)
```

Both **IsNum** and **IsText** return 0 if the expression is NULL.

### Example:

The following example loads an inline table with mixed text and numerical values, and adds two fields to check if the value is a numerical value, respectively a text value.

```
Load *, IsNum(Value), IsText(Value)
Inline [
Value
23
Green
Blue
12
33Red];
```

The resulting table looks like this:

Example 1

| Value | IsNum(Value) | IsText(Value) |
|-------|--------------|---------------|
| 23    | -1           | 0             |
| Green | 0            | -1            |
| Blue  | 0            | -1            |
| 12    | -1           | 0             |
| 33Red | 0            | -1            |

## Mapping functions

This section describes functions for handling mapping tables. A mapping table can be used to replace field values or field names during script execution.

Mapping functions can only be used in the load script.

### Mapping functions overview

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

#### ApplyMap

The **ApplyMap** script function is used for mapping the output of an expression to a previously loaded mapping table.

```
ApplyMap ('mapname', expr [, defaultexpr])
```

### MapSubstring

The **MapSubstring** script function is used to map parts of any expression to a previously loaded mapping table. The mapping is case sensitive and non-iterative, and substrings are mapped from left to right.

```
MapSubstring ('mapname', expr)
```

### ApplyMap

The **ApplyMap** script function is used for mapping the output of an expression to a previously loaded mapping table.

#### Syntax:

```
ApplyMap('map_name', expression [, default_mapping])
```

**Return data type:** dual

#### Arguments:

ApplyMap arguments

| Argument        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| map_name        | The name of a mapping table that has previously been created through the <b>mapping load</b> or the <b>mapping select</b> statement. Its name must be enclosed by single, straight quotation marks.<br><br> <i>If you use this function in a macro expanded variable and refer to a mapping table that does not exist, the function call fails and a field is not created.</i> |
| expression      | The expression, the result of which should be mapped.                                                                                                                                                                                                                                                                                                                                                                                                             |
| default_mapping | If stated, this value will be used as a default value if the mapping table does not contain a matching value for expression. If not stated, the value of expression will be returned as is.                                                                                                                                                                                                                                                                       |

*The output field of ApplyMap should not have the same name as one of its input fields. This may cause unexpected results. Example not to use: `ApplyMap('Map', A) as A`.*

#### Example:

In this example we load a list of salespersons with a country code representing their country of residence. We use a table mapping a country code to a country to replace the country code with the country name. Only three countries are defined in the mapping table, other country codes are mapped to 'Rest of the world'.

```
// Load mapping table of country codes:
map1:
mapping LOAD *
Inline [
```

```
CCode, Country
Sw, Sweden
Dk, Denmark
No, Norway
] ;

// Load list of salesmen, mapping country code to country
// If the country code is not in the mapping table, put Rest of the world
Salespersons:
LOAD *,
ApplyMap('map1', CCode,'Rest of the world') As Country
Inline [
CCode, Salesperson
Sw, John
Sw, Mary
Sw, Per
Dk, Preben
Dk, Olle
No, Ole
Sf, Risttu
] ;

// We don't need the CCode anymore
Drop Field 'CCode';
```

The resulting table (Salespersons) looks like this:

Example 1

| Salesperson | Country           |
|-------------|-------------------|
| John        | Sweden            |
| Mary        | Sweden            |
| Per         | Sweden            |
| Preben      | Denmark           |
| Olle        | Denmark           |
| Ole         | Norway            |
| Risttu      | Rest of the world |

### MapSubstring

The **MapSubstring** script function is used to map parts of any expression to a previously loaded mapping table. The mapping is case sensitive and non-iterative, and substrings are mapped from left to right.

#### Syntax:

```
MapSubstring('map_name', expression)
```

**Return data type:** string

**Arguments:**

MapSubstring arguments

| Argument   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| map_name   | <p>The name of a mapping table previously read by a <b>mapping load</b> or a <b>mapping select</b> statement. The name must be enclosed by single straight quotation marks.</p> <div style="border: 1px solid gray; padding: 5px; margin-top: 10px;">  <p><i>If you use this function in a macro expanded variable and refer to a mapping table that does not exist, the function call fails and a field is not created.</i></p> </div> |
| expression | The expression whose result is to be mapped by substrings.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Example:**

In this example we load a list of product models. Each model has a set of attributes that are described by a composite code. Using the mapping table with MapSubstring, we can expand the attribute codes to a description.

```
map2:
mapping LOAD *
inline [
AttCode, Attribute
R, Red
Y, Yellow
B, Blue
C, Cotton
P, Polyester
S, Small
M, Medium
L, Large
] ;

Productmodels:
LOAD *,
MapSubString('map2', AttCode) as Description
inline [
Model, AttCode
Twixie, R C S
Boomer, B P L
Raven, Y P M
Seedling, R C L
SeedlingPlus, R C L with hood
Younger, B C with patch
MultiStripe, R Y B C S/M/L
] ;
// we don't need the AttCode anymore
Drop Field 'AttCode';
```

The resulting table looks like this:

Example 1

| Model        | Description                               |
|--------------|-------------------------------------------|
| Twixie       | Red Cotton Small                          |
| Boomer       | Blue Polyester Large                      |
| Raven        | Yellow Polyester Medium                   |
| Seedling     | Red Cotton Large                          |
| SeedlingPlus | Red Cotton Large with hood                |
| Younger      | Blue Cotton with patch                    |
| MultiStripe  | Red Yellow Blue Cotton Small/Medium/Large |

### Mathematical functions

This section describes functions for mathematical constants and Boolean values. These functions do not have any parameters, but the parentheses are still required.

All functions can be used in both the load script and in chart expressions.

#### **e**

The function returns the base of the natural logarithms, **e** (2.71828...).

```
e()
```

#### **false**

The function returns a dual value with text value 'False' and numeric value 0, which can be used as logical false in expressions.

```
false()
```

#### **pi**

The function returns the value of  $\pi$  (3.14159...).

```
pi()
```

#### **rand**

The function returns a random number between 0 and 1. This can be used to create sample data.

```
rand()
```

#### **Example:**

This example script creates a table of 1000 records with randomly selected upper case characters, that is, characters in the range 65 to 91 (65+26).

Load

```
Chr(Floor(rand() * 26) + 65) as UCaseChar,
```

```
RecNo() as ID
Autogenerate 1000;
```

### true

The function returns a dual value with text value 'True' and numeric value -1, which can be used as logical true in expressions.

```
true()
```

## NULL functions

This section describes functions for returning or detecting NULL values.

All functions can be used in both the load script and in chart expressions.

### NULL functions overview

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

### Null

The **Null** function returns a NULL value.

```
NULL ()
```

### IsNull

The **IsNull** function tests if the value of an expression is NULL and if so, returns -1 (True), otherwise 0 (False).

```
IsNull (expr)
```

### EmptyIsNull

The **EmptyIsNull** function converts empty strings to NULL. Hence, it returns NULL if the parameter is an empty string, otherwise it returns the parameter.

### Syntax:

```
EmptyIsNull (exp)
```

Examples and results:

#### Scripting examples

| Example                                      | Result                                                                                                                                                                    |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>EmptyIsNull(AdditionalComments)</code> | This expression will return as null any empty string values of the <i>AdditionalComments</i> field, instead of empty strings. Non-empty strings and numbers are returned. |

| Example                                                       | Result                                                                                                                                                                                                                                                          |
|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>EmptyIsNull(PurgeChar<br/>(PhoneNumber, ' -()'))</code> | This expression will strip any dashes, spaces and parentheses from the <i>PhoneNumber</i> field. If there are no characters left, the <code>EmptyIsNull</code> function returns the empty string as null; an empty phone number is the same as no phone number. |

### IsNull

The **IsNull** function tests if the value of an expression is NULL and if so, returns -1 (True), otherwise 0 (False).

#### Syntax:

**IsNull** (expr )

*A string with length zero is not considered as a NULL and will cause **IsNull** to return False.*

#### Example: Load script

In this example, an inline table with four rows is loaded, where the first three lines contain either nothing, - or 'NULL' in the Value column. We convert these values to true NULL value representations with the middle preceding **LOAD** using the **Null** function.

The first preceding **LOAD** adds a field checking if the value is NULL, using the **IsNull** function.

NullsDetectedAndConverted:

```
LOAD *,
If(IsNull(ValueNullConv), 'T', 'F') as IsItNull;
```

```
LOAD *,
If(len(trim(Value))= 0 or Value='NULL' or Value='-', Null(), Value) as ValueNullConv;
```

```
LOAD * Inline
[ID, Value
0,
1, NULL
2, -
3, Value];
```

This is the resulting table. In the ValueNullConv column, the NULL values are represented by -.

Example 1

| ID | Value | ValueNullConv | IsItNull |
|----|-------|---------------|----------|
| 0  | -     | -             | T        |
| 1  | NULL  | -             | T        |
| 2  | -     | -             | T        |
| 3  | Value | Value         | F        |

### NULL

The **Null** function returns a NULL value.

#### Syntax:

```
Null ()
```

#### Example: Load script

In this example, an inline table with four rows is loaded, where the first three lines contain either nothing, - or 'NULL' in the Value column. We want to convert these values to true NULL value representations.

The middle preceding **LOAD** performs the conversion using the **Null** function.

The first preceding **LOAD** adds a field checking if the value is **NULL**, just for illustration purposes in this example.

NullsDetectedAndConverted:

```
LOAD *,
If(IsNull(ValueNullConv), 'T', 'F') as IsItNull;

LOAD *,
If(len(trim(Value))= 0 or Value='NULL' or Value='-', Null(), Value) as ValueNullConv;

LOAD * Inline
[ID, Value
0,
1,NULL
2,-
3,value];
```

This is the resulting table. In the ValueNullConv column, the NULL values are represented by -.

Example 1

| ID | Value | ValueNullConv | IsItNull |
|----|-------|---------------|----------|
| 0  | -     | -             | T        |
| 1  | NULL  | -             | T        |
| 2  | -     | -             | T        |
| 3  | Value | Value         | F        |

### Range functions

The range functions are functions that take an array of values and produce a single value as a result. All range functions can be used in both the load script and in chart expressions.

For example, in a chart, a range function can calculate a single value from an inter-record array. In the load script, a range function can calculate a single value from an array of values in an internal table.

*Range functions supersede the following general numeric functions: **numsum**, **numavg**, **numcount**, **nummin** and **nummax**. These can still be used, but are not recommended.*

### Basic range functions

#### RangeMax

**RangeMax()** returns the highest numeric value found within the expression or field.

```
RangeMax (first_expr[, Expression])
```

#### RangeMaxString

**RangeMaxString()** returns the last value in the text sort order that it finds in the expression or field.

```
RangeMaxString (first_expr[, Expression])
```

#### RangeMin

**RangeMin()** returns the lowest numeric values found within the expression or field.

```
RangeMin (first_expr[, Expression])
```

#### RangeMinString

**RangeMinString()** returns the first value in the text sort order that it finds in the expression or field.

```
RangeMinString (first_expr[, Expression])
```

#### RangeMode

**RangeMode()** finds the most commonly occurring value (mode value) in the expression or field.

```
RangeMode (first_expr[, Expression])
```

#### RangeOnly

**RangeOnly()** is a **dual** function that returns a value if the expression evaluates to one unique value. If this is not the case then **NULL** is returned.

```
RangeOnly (first_expr[, Expression])
```

#### RangeSum

**RangeSum()** returns the sum of a range of values. All non-numeric values are treated as 0, unlike the **+** operator.

```
RangeSum (first_expr[, Expression])
```

### Counter range functions

#### RangeCount

**RangeCount()** returns the number of values, both text and numeric, in the expression or field.

```
RangeCount (first_expr[, Expression])
```

### RangeMissingCount

**RangeMissingCount()** returns the number of non-numeric values (including NULL) in the expression or field.

```
RangeMissingCount (first_expr[, Expression])
```

### RangeNullCount

**RangeNullCount()** finds the number of NULL values in the expression or field.

```
RangeNullCount (first_expr[, Expression])
```

### RangeNumericCount

**RangeNumericCount()** finds the number of numeric values in an expression or field.

```
RangeNumericCount (first_expr[, Expression])
```

### RangeTextCount

**RangeTextCount()** returns the number of text values in an expression or field.

```
RangeTextCount (first_expr[, Expression])
```

## Statistical range functions

### RangeAvg

**RangeAvg()** returns the average of a range. Input to the function can be either a range of values or an expression.

```
RangeAvg (first_expr[, Expression])
```

### RangeCorrel

**RangeCorrel()** returns the correlation coefficient for two sets of data. The correlation coefficient is a measure of the relationship between the data sets.

```
RangeCorrel (x_values , y_values[, Expression])
```

### RangeFractile

**RangeFractile()** returns the value that corresponds to the n-th **fractile** (quantile) of a range of numbers.

```
RangeFractile (fractile, first_expr[, Expression])
```

### RangeKurtosis

**RangeKurtosis()** returns the value that corresponds to the kurtosis of a range of numbers.

```
RangeKurtosis (first_expr[, Expression])
```

### RangeSkew

**RangeSkew()** returns the value corresponding to the skewness of a range of numbers.

```
RangeSkew (first_expr[, Expression])
```

### RangeStdev

**RangeStdev()** finds the standard deviation of a range of numbers.

```
RangeStdev (expr1[, Expression])
```

### Financial range functions

#### RangeIRR

**RangeIRR()** returns the internal rate of return for a series of cash flows represented by the input values.

```
RangeIRR (value[, value][, Expression])
```

#### RangeNPV

**RangeNPV()** returns the net present value of an investment based on a discount rate and a series of future payments (negative values) and incomes (positive values). The result has a default number format of **money**.

```
RangeNPV (discount_rate, value[, value][, Expression])
```

#### RangeXIRR

**RangeXIRR()** returns the internal rate of return for a schedule of cash flows that is not necessarily periodic. To calculate the internal rate of return for a series of periodic cash flows, use the **RangeIRR** function.

```
RangeXIRR (values, dates[, Expression])
```

#### RangeXNPV

**RangeXNPV()** returns the net present value for a schedule of cash flows that is not necessarily periodic. The result has a default number format of money. To calculate the net present value for a series of periodic cash flows, use the **RangeNPV** function.

```
RangeXNPV (discount_rate, values, dates[, Expression])
```

### RangeAvg

**RangeAvg()** returns the average of a range. Input to the function can be either a range of values or an expression.

#### Syntax:

```
RangeAvg (first_expr[, Expression])
```

**Return data type:** numeric

#### Arguments:

The argument of this function may contain inter-record functions which in themselves return a list of values.

- **first\_expr:** The expression or field containing the data to be averaged.
- **Expression:** Optional expressions or fields containing additional data to be averaged. Multiple additional expressions can be used.

#### Limitations:

If no numeric value is found, NULL is returned.

### Examples:

#### Examples and results

| Example                   | Result             |
|---------------------------|--------------------|
| RangeAvg (1,2,4)          | Returns 2.33333333 |
| RangeAvg (1, 'xyz')       | Returns 1          |
| RangeAvg (null( ), 'abc') | Returns NULL       |

### Example: (using expression)

```
RangeAvg (Above(MyField),0,3))
```

Returns a sliding average of the result of the range of three values of **MyField** calculated on the current row and two rows above the current row. By specifying the third argument as 3, the **Above()** function returns three values, where there are sufficient rows above, which are taken as input to the **RangeAvg()** function.

*Disable sorting of **MyField** to ensure that example works as expected.*

#### Example expression output

| MyField | RangeAvg (Above (MyField,0,3)) | Explanation                                                        |
|---------|--------------------------------|--------------------------------------------------------------------|
| 10      | 10                             | Because this is the top row, the range consists of one value only. |
| 2       | 6                              | There is only one row above this row, so the range is: 10,2.       |
| 8       | 6.666666667                    | The equivalent to RangeAvg(10,2,8)                                 |
| 18      | 9.333333333                    | -                                                                  |
| 5       | 10.333333333                   | -                                                                  |
| 9       | 10.666666667                   | -                                                                  |

### Data used in examples:

```
RangeTab:
LOAD * INLINE [
MyField
10
2
8
18
5
9
] ;
```

### Example: (in table form)

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
RangeTab3:
LOAD recno() as RangeID, RangeAvg(Field1,Field2,Field3) as MyRangeAvg INLINE [
Field1, Field2, Field3
10,5,6
2,3,7
8,2,8
18,11,9
5,5,9
9,4,2
];
```

The resulting table shows the returned values of MyRangeAvg for each of the records in the table.

Example output in table form

| RangeID | MyRangeAvg |
|---------|------------|
| 1       | 7          |
| 2       | 4          |
| 3       | 6          |
| 4       | 12.666     |
| 5       | 6.333      |
| 6       | 5          |

### RangeCorrel

**RangeCorrel()** returns the correlation coefficient for two sets of data. The correlation coefficient is a measure of the relationship between the data sets.

#### Syntax:

```
RangeCorrel (x_values , y_values[, Expression])
```

**Return data type:** numeric

Data series should be entered as (x,y) pairs. For example, to evaluate two series of data, array 1 and array 2, where the array 1 = 2,6,9 and array 2 = 3,8,4 you would write `RangeCorrel (2,3,6,8,9,4)` which returns 0.269.

#### Arguments:

- **x-value, y-value:** Each value represents a single value or a range of values as returned by an inter-record functions with a third optional parameter. Each value or range of values must

correspond to an **x-value** or a range of **y-values**.

- **Expression:** Optional expressions or fields containing the range of data to be measured.

### Limitations:

The function needs at least two pairs of coordinates to be calculated.

Text values, NULL values and missing values return NULL.

### Examples:

Examples and results

| Example                                | Result        |
|----------------------------------------|---------------|
| <code>RangeCorrel (2,3,6,8,9,4)</code> | Returns 0.269 |

## RangeCount

**RangeCount()** returns the number of values, both text and numeric, in the expression or field.

### Syntax:

```
RangeCount (first_expr[, Expression])
```

**Return data type:** integer

### Arguments:

The argument of this function may contain inter-record functions which in themselves return a list of values.

- `first_expr`: The expression or field containing the data to be counted.
- `Expression`: Optional expressions or fields containing additional data to be counted.

### Limitations:

NULL values are not counted.

### Examples:

Examples and results

| Example                                    | Result    |
|--------------------------------------------|-----------|
| <code>RangeCount (1,2,4)</code>            | Returns 3 |
| <code>RangeCount (2, 'xyz')</code>         | Returns 2 |
| <code>RangeCount (null( ))</code>          | Returns 0 |
| <code>RangeCount (2, 'xyz', null())</code> | Returns 2 |

### Example: (using expression)

`RangeCount (Above(MyField,1,3))`

Returns the number of values contained in the three results of **MyField**. By specifying the second and third arguments of the **Above()** function as 3, it returns the values from the three fields above the current row, where there are sufficient rows, which are taken as input to the **RangeSum()** function.

Example expression output

| MyField | RangeCount(Above(MyField,1,3)) |
|---------|--------------------------------|
| 10      | 0                              |
| 2       | 1                              |
| 8       | 2                              |
| 18      | 3                              |
| 5       | 3                              |
| 9       | 3                              |

### Data used in examples:

```
RangeTab:
LOAD * INLINE [
MyField
10
2
8
18
5
9
] ;
```

### Example: (in table form)

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
RangeTab3:
LOAD recno() as RangeID, RangeCount(Field1,Field2,Field3) as MyRangeCount INLINE [
Field1, Field2, Field3
10,5,6
2,3,7
8,2,8
18,11,9
5,5,9
9,4,2
] ;
```

The resulting table shows the returned values of **MyRangeCount** for each of the records in the table.

Example output in table form

| RangeID | MyRangeCount |
|---------|--------------|
| 1       | 3            |
| 2       | 3            |
| 3       | 3            |
| 4       | 3            |
| 5       | 3            |
| 6       | 3            |

### RangeFractile

**RangeFractile()** returns the value that corresponds to the n-th **fractile** (quantile) of a range of numbers.

*RangeFractile() uses linear interpolation between closest ranks when calculating the fractile.*

#### Syntax:

```
RangeFractile(fractile, first_expr[, Expression])
```

**Return data type:** numeric

#### Arguments:

The argument of this function may contain inter-record functions which in themselves return a list of values.

- **fractile:** A number between 0 and 1 corresponding to the fractile (quantile expressed as a fraction) to be calculated.
- **first\_expr:** The expression or field containing the data to be measured.
- **Expression:** Optional expressions or fields containing the range of data to be measured.

#### Examples:

Examples and results

| Example                      | Result       |
|------------------------------|--------------|
| RangeFractile (0.24,1,2,4,6) | Returns 1.72 |
| RangeFractile(0.5,1,2,3,4,6) | Returns 3    |
| RangeFractile (0.5,1,2,5,6)  | Returns 3.5  |

#### Example: (using expression)

```
RangeFractile (0.5, Above(Sum(MyField),0,3))
```

## 9 Script syntax and chart functions

---

In this example, the inter-record function **Above()** contains the optional offset and count arguments. This produces a range of results that can be used as input to the any of the range functions. In this case, `Above(Sum(MyField),0,3)` returns the values of `MyField` for the current row and the two rows above. These values provide the input to the **RangeFractile()** function. So, for the bottom row in the table below, this is the equivalent of `RangeFractile(0.5, 3,4,6)`, that is, calculating the 0.5 fractile for the series 3, 4, and 6. The first two rows in the table below, the number of values in the range is reduced accordingly, where there no rows above the current row. Similar results are produced for other inter-record functions.

Example expression output

| MyField | RangeFractile(0.5, Above(Sum(MyField),0,3)) |
|---------|---------------------------------------------|
| 1       | 1                                           |
| 2       | 1.5                                         |
| 3       | 2                                           |
| 4       | 3                                           |
| 5       | 4                                           |
| 6       | 5                                           |

### Data used in examples:

```
RangeTab:
LOAD * INLINE [
MyField
1
2
3
4
5
6
] ;
```

### Example: (in table form)

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
RangeTab:
LOAD recno() as RangeID, RangeFractile(0.5,Field1,Field2,Field3) as MyRangeFrac INLINE [
Field1, Field2, Field3
10,5,6
2,3,7
8,2,8
18,11,9
5,5,9
9,4,2
];
```

The resulting table shows the returned values of `MyRangeFrac` for each of the records in the table.

Example output in table form

| RangeID | MyRangeFrac |
|---------|-------------|
| 1       | 6           |
| 2       | 3           |
| 3       | 8           |
| 4       | 11          |
| 5       | 5           |
| 6       | 4           |

### RangeIRR

**RangeIRR()** returns the internal rate of return for a series of cash flows represented by the input values.

The internal rate of return is the interest rate received for an investment consisting of payments (negative values) and income (positive values) that occur at regular periods.

This function uses a simplified version of the Newton method for calculating the internal rate of return (IRR).

#### Syntax:

```
RangeIRR(value[, value][, Expression])
```

**Return data type:** numeric

#### Arguments:

- **value:** A single value or a range of values as returned by an inter record function with a third optional parameter. The function needs at least one positive and one negative value to be calculated.
- **Expression:** Optional expressions or fields containing the range of data to be measured.

#### Limitations:

Text values, NULL values and missing values are disregarded.

#### Example 1:

`RangeIRR(-70000,12000,15000,18000,21000,26000)` returns **0.0866**.

#### Example 2:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
RangeTab3:
LOAD *,
recno() as RangeID,
RangeIRR(Field1,Field2,Field3) as RangeIRR;
```

```
LOAD * INLINE [
Field1|Field2|Field3
-10000|5000|6000
-2000|NULL|7000
-8000|'abc'|8000
-1800|11000|9000
-5000|5000|9000
-9000|4000|2000
] (delimiter is '|');
```

The resulting table shows the returned values of RangeIRR for each of the records in the table:

Example results

| RangeID | RangeIRR |
|---------|----------|
| 1       | 0.0639   |
| 2       | 0.8708   |
| 3       | -        |
| 4       | 5.8419   |
| 5       | 0.9318   |
| 6       | -0.2566  |

### RangeKurtosis

**RangeKurtosis()** returns the value that corresponds to the kurtosis of a range of numbers.

#### Syntax:

```
RangeKurtosis(first_expr[, Expression])
```

**Return data type:** numeric

#### Arguments:

The argument of this function may contain inter-record functions which in themselves return a list of values.

- **first\_expr:** The expression or field containing the data to be measured.
- **Expression:** Optional expressions or fields containing the range of data to be measured.

#### Limitations:

If no numeric value is found, NULL is returned.

#### Examples:

Examples and results

| Example                 | Result                    |
|-------------------------|---------------------------|
| RangeKurtosis (1,2,4,7) | Returns -0.28571428571429 |

### RangeMax

**RangeMax()** returns the highest numeric value found within the expression or field.

#### Syntax:

```
RangeMax (first_expr[, Expression])
```

**Return data type:** numeric

#### Arguments:

- **first\_expr:** The expression or field containing the data to be measured.
- **Expression:** Optional expressions or fields containing the range of data to be measured. Multiple additional expressions can be used.

#### Limitations:

If no numeric value is found, NULL is returned.

#### Examples:

Examples and results

| Example                   | Result       |
|---------------------------|--------------|
| RangeMax (1,2,4)          | Returns 4    |
| RangeMax (1, 'xyz')       | Returns 1    |
| RangeMax (null( ), 'abc') | Returns NULL |

#### Example: (using expression)

```
RangeMax (Above(MyField,0,3))
```

Returns the maximum value in the range of three values of **MyField** calculated on the current row and two rows above the current row. By specifying the third argument as 3, the **Above()** function returns three values, where there are sufficient rows above, which are taken as input to the **RangeMax()** function.

*Disable sorting of **MyField** to ensure that example works as expected.*

Example expression output

| MyField | RangeMax (Above(Sum(MyField),1,3)) |
|---------|------------------------------------|
| 10      | 10                                 |
| 2       | 10                                 |
| 8       | 10                                 |

| MyField | RangeMax (Above(Sum(MyField),1,3)) |
|---------|------------------------------------|
| 18      | 18                                 |
| 5       | 18                                 |
| 9       | 18                                 |

### Data used in examples:

```
RangeTab:
LOAD * INLINE [
MyField
10
2
8
18
5
9
] ;
```

### Example: (in table form)

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
RangeTab3:
LOAD recno() as RangeID, RangeMax(Field1,Field2,Field3) as MyRangeMax INLINE [
Field1, Field2, Field3
10,5,6
2,3,7
8,2,8
18,11,9
5,5,9
9,4,2
] ;
```

The resulting table shows the returned values of MyRangeMax for each of the records in the table.

Example output in table form

| RangeID | MyRangeMax |
|---------|------------|
| 1       | 10         |
| 2       | 7          |
| 3       | 8          |
| 4       | 18         |
| 5       | 9          |
| 6       | 9          |

### RangeMaxString

**RangeMaxString()** returns the last value in the text sort order that it finds in the expression or field.

### Syntax:

```
RangeMaxString (first_expr[, Expression])
```

**Return data type:** string

### Arguments:

The argument of this function may contain inter-record functions which in themselves return a list of values.

- `first_expr`: The expression or field containing the data to be measured.
- `Expression`: Optional expressions or fields containing the range of data to be measured. Multiple additional expressions can be used.

### Examples:

Examples and results

| Example                                   | Result        |
|-------------------------------------------|---------------|
| <code>RangeMaxString (1,2,4)</code>       | Returns 4     |
| <code>RangeMaxString ('xyz','abc')</code> | Returns 'xyz' |
| <code>RangeMaxString (5,'abc')</code>     | Returns 'abc' |
| <code>RangeMaxString (null( ))</code>     | Returns NULL  |

### Example: (using expression)

```
RangeMaxString (Above(MaxString(MyField),0,3))
```

Returns the last (in text sort order) of the three results of the **MaxString(MyField)** function evaluated on the current row and two rows above the current row.

*Disable sorting of **MyField** to ensure that example works as expected.*

Example expression output

| MyField | RangeMaxString(Above(MaxString(MyField),0,3)) |
|---------|-----------------------------------------------|
| 10      | 10                                            |
| abc     | abc                                           |
| 8       | abc                                           |
| def     | def                                           |
| xyz     | xyz                                           |
| 9       | xyz                                           |

### Data used in examples:

```
RangeTab:
LOAD * INLINE [
MyField
10
'abc'
8
'def'
'xyz'
9
] ;
```

### RangeMin

**RangeMin()** returns the lowest numeric values found within the expression or field.

#### Syntax:

```
RangeMin (first_expr[, Expression])
```

**Return data type:** numeric

#### Arguments:

- **first\_expr:** The expression or field containing the data to be measured.
- **Expression:** Optional expressions or fields containing the range of data to be measured. Multiple additional expressions can be used.

#### Limitations:

If no numeric value is found, NULL is returned.

#### Examples:

Examples and results

| Example                   | Result       |
|---------------------------|--------------|
| RangeMin (1,2,4)          | Returns 1    |
| RangeMin (1,'xyz')        | Returns 1    |
| RangeMin (null( ), 'abc') | Returns NULL |

#### Example: (using expression)

```
RangeMin (Above(MyField,0,3))
```

Returns the minimum value in the range of three values of **MyField** calculated on the current row and two rows above the current row. By specifying the third argument as 3, the **Above()** function returns three values, where there are sufficient rows above, which are taken as input to the **RangeMin()** function.

Example expression output

| MyField | RangeMin(Above(MyField,0,3)) |
|---------|------------------------------|
| 10      | 10                           |
| 2       | 2                            |
| 8       | 2                            |
| 18      | 2                            |
| 5       | 5                            |
| 9       | 5                            |

### Data used in examples:

```
RangeTab:
LOAD * INLINE [
MyField
10
2
8
18
5
9
] ;
```

### Example: (in table form)

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
RangeTab3:
LOAD recno() as RangeID, RangeMin(Field1,Field2,Field3) as MyRangeMin INLINE [
Field1, Field2, Field3
10,5,6
2,3,7
8,2,8
18,11,9
5,5,9
9,4,2
] ;
```

The resulting table shows the returned values of MyRangeMin for each of the records in the table.

Example output in table form

| RangeID | MyRangeMin |
|---------|------------|
| 1       | 5          |
| 2       | 2          |
| 3       | 2          |
| 4       | 9          |

| RangeID | MyRangeMin |
|---------|------------|
| 5       | 5          |
| 6       | 2          |

### RangeMinString

**RangeMinString()** returns the first value in the text sort order that it finds in the expression or field.

#### Syntax:

```
RangeMinString(first_expr[, Expression])
```

**Return data type:** string

#### Arguments:

The argument of this function may contain inter-record functions which in themselves return a list of values.

- **first\_expr:** The expression or field containing the data to be measured.
- **Expression:** Optional expressions or fields containing the range of data to be measured. Multiple additional expressions can be used.

#### Examples and results:

| Examples                                   | Results       |
|--------------------------------------------|---------------|
| <code>RangeMinString (1,2,4)</code>        | Returns 1     |
| <code>RangeMinString ('xyz', 'abc')</code> | Returns 'abc' |
| <code>RangeMinString (5, 'abc')</code>     | Returns 5     |
| <code>RangeMinString (null( ))</code>      | Returns NULL  |

#### Example: (using expression)

```
RangeMinString (Above(MinString(MyField),0,3))
```

Returns the first (in text sort order) of the three results of the **MinString(MyField)** function evaluated on the current row and two rows above the current row.

*Disable sorting of **MyField** to ensure that example works as expected.*

#### Example expression output

| MyField | RangeMinString(Above(MinString(MyField),0,3)) |
|---------|-----------------------------------------------|
| 10      | 10                                            |
| abc     | 10                                            |

| MyField | RangeMinString(Above(MinString(MyField),0,3)) |
|---------|-----------------------------------------------|
| 8       | 8                                             |
| def     | 8                                             |
| xyz     | 8                                             |
| 9       | 9                                             |

### Data used in examples:

```
RangeTab:
LOAD * INLINE [
MyField
10
'abc'
8
'def'
'xyz'
9
] ;
```

### RangeMissingCount

**RangeMissingCount()** returns the number of non-numeric values (including NULL) in the expression or field.

#### Syntax:

```
RangeMissingCount (first_expr[, Expression])
```

**Return data type:** integer

#### Arguments:

The argument of this function may contain inter-record functions which in themselves return a list of values.

- **first\_expr:** The expression or field containing the data to be counted.
- **Expression:** Optional expressions or fields containing the range of data to be counted.

#### Examples:

Examples and results

| Example                     | Result    |
|-----------------------------|-----------|
| RangeMissingCount (1,2,4)   | Returns 0 |
| RangeMissingCount (5,'abc') | Returns 1 |
| RangeMissingCount (null( )) | Returns 1 |

#### Example: (using expression)

```
RangeMissingCount (Above(MinString(MyField),0,3))
```

## 9 Script syntax and chart functions

Returns the number of non-numeric values in the three results of the **MinString(MyField)** function evaluated on the current row and two rows above the current row.

*Disable sorting of **MyField** to ensure that example works as expected.*

Example expression output

| MyField | RangeMissingCount(Above (MinString(MyField),0,3)) | Explanation                                                                                             |
|---------|---------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| 10      | 2                                                 | Returns 2 because there are no rows above this row so 2 of the 3 values are missing.                    |
| abc     | 2                                                 | Returns 2 because there is only 1 row above the current row and the current row is non-numeric ('abc'). |
| 8       | 1                                                 | Returns 1 because 1 of the 3 rows includes a non-numeric ('abc').                                       |
| def     | 2                                                 | Returns 2 because 2 of the 3 rows include non-numeric values ('def' and 'abc').                         |
| xyz     | 2                                                 | Returns 2 because 2 of the 3 rows include non-numeric values ('xyz' and 'def').                         |
| 9       | 2                                                 | Returns 2 because 2 of the 3 rows include non-numeric values ('xyz' and 'def').                         |

### Data used in examples:

```
RangeTab:
LOAD * INLINE [
MyField
10
'abc'
8
'def'
'xyz'
9
] ;
```

### RangeMode

**RangeMode()** finds the most commonly occurring value (mode value) in the expression or field.

#### Syntax:

```
RangeMode (first_expr {, Expression})
```

**Return data type:** numeric

#### Arguments:

The argument of this function may contain inter-record functions which in themselves return a list of values.

## 9 Script syntax and chart functions

- `first_expr`: The expression or field containing the data to be measured.
- `Expression`: Optional expressions or fields containing the range of data to be measured.

### Limitations:

If more than one value shares the highest frequency, NULL is returned.

### Examples:

Examples and results

| Example                               | Result       |
|---------------------------------------|--------------|
| <code>RangeMode (1,2,9,2,4)</code>    | Returns 2    |
| <code>RangeMode ('a',4, 'a',4)</code> | Returns NULL |
| <code>RangeMode (null( ))</code>      | Returns NULL |

### Example: (using expression)

```
RangeMode (Above(MyField,0,3))
```

Returns the most commonly occurring value in the three results of **MyField** evaluated on the current row and two rows above the current row. By specifying the third argument as 3, the **Above()** function returns three values, where there are sufficient rows above, which are taken as input to the **RangeMode()** function.

*Disable sorting of **MyField** to ensure that example works as expected.*

Example expression output

| MyField | RangeMode(Above(MyField,0,3))                                                                  |
|---------|------------------------------------------------------------------------------------------------|
| 10      | Returns 10 because there are no rows above so the single value is the most commonly occurring. |
| 2       | -                                                                                              |
| 8       | -                                                                                              |
| 18      | -                                                                                              |
| 5       | -                                                                                              |
| 9       | -                                                                                              |

### Data used in examples:

```
RangeTab:
LOAD * INLINE [
MyField
10
2
8
18
```

```
5
9
] ;
```

### Example: (in table form)

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
RangeTab3:
LOAD recno() as RangeID, RangeMode(Field1,Field2,Field3) as MyRangeMode INLINE [
Field1, Field2, Field3
10,5,6
2,3,7
8,2,8
18,11,9
5,5,9
9,4,2
];
```

The resulting table shows the returned values of MyRangeMode for each of the records in the table.

Example output in table form

| RangeID | MyRangeMode |
|---------|-------------|
| 1       | -           |
| 2       | -           |
| 3       | 8           |
| 4       | -           |
| 5       | 5           |
| 6       | -           |

### RangeNPV

**RangeNPV()** returns the net present value of an investment based on a discount rate and a series of future payments (negative values) and incomes (positive values). The result has a default number format of **money**.

For cash flows that are not necessarily periodic, see *RangeXNPV* (page 1510).

#### Syntax:

```
RangeNPV (discount_rate, value[,value][, Expression])
```

**Return data type:** numeric

**Arguments:**

- `discount_rate`: The interest rate per period.
- `value`: A payment or income occurring at the end of each period. Each value may be a single value or a range of values as returned by an inter-record function with a third optional parameter.
- `Expression`: Optional expressions or fields containing the range of data to be measured.

**Limitations:**

Text values, NULL values and missing values are disregarded.

**Example 1:**

`RangeNPV(0.1, -10000, 3000, 4200, 6800)` returns **1188.44**.

**Example 2:**

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
RangeTab3:
LOAD *,
recno() as RangeID,
RangeNPV(Field1,Field2,Field3) as RangeNPV;
LOAD * INLINE [
Field1|Field2|Field3
10|5|-6000
2|NULL|7000
8|'abc'|8000
18|11|9000
5|5|9000
9|4|2000
] (delimiter is '|');
```

The resulting table shows the returned values of `RangeNPV` for each of the records in the table:

Example results

| RangeID | RangeNPV |
|---------|----------|
| 1       | \$-49.13 |
| 2       | \$777.78 |
| 3       | \$98.77  |
| 4       | \$25.51  |
| 5       | \$250.83 |
| 6       | \$20.40  |

### RangeNullCount

**RangeNullCount()** finds the number of NULL values in the expression or field.

#### Syntax:

```
RangeNullCount (firstexpr [, Expression])
```

**Return data type:** integer

#### Arguments:

The argument of this function may contain inter-record functions which in themselves return a list of values.

- `first_expr`: The expression or field containing the data to be measured.
- `Expression`: Optional expressions or fields containing the range of data to be measured.

#### Examples:

Examples and results

| Example                                        | Result    |
|------------------------------------------------|-----------|
| <code>RangeNullCount (1,2,4)</code>            | Returns 0 |
| <code>RangeNullCount (5, 'abc')</code>         | Returns 0 |
| <code>RangeNullCount (null( ), null( ))</code> | Returns 2 |

#### Example: (using expression)

```
RangeNullCount (Above(Sum(MyField),0,3))
```

Returns the number of NULL values in the three results of the **Sum(MyField)** function evaluated on the current row and two rows above the current row.

*Copying **MyField** in example below will not result in NULL value.*

*Disable sorting of **MyField** to ensure that example works as expected.*

Example expression output

| MyField | RangeNullCount(Above(Sum(MyField),0,3))                                                                       |
|---------|---------------------------------------------------------------------------------------------------------------|
| 10      | Returns 2 because there are no rows above this row so 2 of the 3 values are missing (=NULL).                  |
| 'abc'   | Returns 1 because there is only one row above the current row, so one of the three values is missing (=NULL). |
| 8       | Returns 0 because none of the three rows is a NULL value.                                                     |

### Data used in examples:

```
RangeTab:
LOAD * INLINE [
MyField
10
'abc'
8
] ;
```

### RangeNumericCount

**RangeNumericCount()** finds the number of numeric values in an expression or field.

#### Syntax:

```
RangeNumericCount(first_expr[, Expression])
```

**Return data type:** integer

#### Arguments:

The argument of this function may contain inter-record functions which in themselves return a list of values.

- **first\_expr:** The expression or field containing the data to be measured.
- **Expression:** Optional expressions or fields containing the range of data to be measured.

#### Examples:

Examples and results

| Example                     | Result    |
|-----------------------------|-----------|
| RangeNumericCount (1,2,4)   | Returns 3 |
| RangeNumericCount (5,'abc') | Returns 1 |
| RangeNumericCount (null( )) | Returns 0 |

#### Example: (using expression)

```
RangeNumericCount (Above(MaxString(MyField),0,3))
```

Returns the number of numeric values in the three results of the **MaxString(MyField)** function evaluated on the current row and two rows above the current row.

*Disable sorting of **MyField** to ensure that example works as expected.*

Example expression output

| MyField | RangeNumericCount(Above(MaxString(MyField),0,3)) |
|---------|--------------------------------------------------|
| 10      | 1                                                |

| MyField | RangeNumericCount(Above(MaxString(MyField),0,3)) |
|---------|--------------------------------------------------|
| abc     | 1                                                |
| 8       | 2                                                |
| def     | 1                                                |
| xyz     | 1                                                |
| 9       | 1                                                |

### Data used in examples:

```
RangeTab:
LOAD * INLINE [
MyField
10
'abc'
8
def
xyz
9
] ;
```

### RangeOnly

**RangeOnly()** is a **dual** function that returns a value if the expression evaluates to one unique value. If this is not the case then **NULL** is returned.

#### Syntax:

```
RangeOnly (first_expr[, Expression])
```

**Return data type:** dual

#### Arguments:

The argument of this function may contain inter-record functions which in themselves return a list of values.

- `first_expr`: The expression or field containing the data to be measured.
- `Expression`: Optional expressions or fields containing the range of data to be measured.

#### Examples:

Examples and results

| Example                                 | Result        |
|-----------------------------------------|---------------|
| <code>RangeOnly (1,2,4)</code>          | Returns NULL  |
| <code>RangeOnly (5,'abc')</code>        | Returns NULL  |
| <code>RangeOnly (null( ), 'abc')</code> | Returns 'abc' |
| <code>RangeOnly(10,10,10)</code>        | Returns 10    |

### RangeSkew

**RangeSkew()** returns the value corresponding to the skewness of a range of numbers.

**Syntax:**

```
RangeSkew (first_expr[, Expression])
```

**Return data type:** numeric

**Arguments:**

The argument of this function may contain inter-record functions which in themselves return a list of values.

- `first_expr`: The expression or field containing the data to be measured.
- `Expression`: Optional expressions or fields containing the range of data to be measured.

**Limitations:**

If no numeric value is found, NULL is returned.

**Examples:**

Examples and results

| Example                                         | Result                                                                                                                                                                                                           |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>rangeskew (1,2,4)</code>                  | Returns 0.93521952958283                                                                                                                                                                                         |
| <code>rangeskew (above (SalesValue,0,3))</code> | Returns a sliding skewness of the range of three values returned from the <code>above()</code> function calculated on the current row and the two rows above the current row, as seen in the below table output. |

Example output in table form

| CustID | RangeSkew(Above(SalesValue,0,3))                                                                                           |
|--------|----------------------------------------------------------------------------------------------------------------------------|
| 1-20   | -, -, 0.5676, 0.8455, 1.0127, -0.8741, 1.7243, -1.7186, 1.5518, 1.4332, 0, 1.1066, 1.3458, 1.5636, 1.5439, 0.6952, -0.3766 |

**Data used in examples:**

```
salesTable:
LOAD recno() as CustID, * inline [
SalesValue
101
163
126
139
167
86
83

176  
113  
95  
32  
42  
92  
61  
21  
] ;

### RangeStdev

**RangeStdev()** finds the standard deviation of a range of numbers.

#### Syntax:

```
RangeStdev(first_expr[, Expression])
```

**Return data type:** numeric

#### Arguments:

The argument of this function may contain inter-record functions which in themselves return a list of values.

- `first_expr`: The expression or field containing the data to be measured.
- `Expression`: Optional expressions or fields containing the range of data to be measured.

#### Limitations:

If no numeric value is found, NULL is returned.

#### Examples:

Examples and results

| Example                                           | Result                                                                                                                                                                                                           |
|---------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>RangeStdev (1,2,4)</code>                   | Returns 1.5275252316519                                                                                                                                                                                          |
| <code>RangeStdev (null( ))</code>                 | Returns NULL                                                                                                                                                                                                     |
| <code>RangeStdev (above (SalesValue),0,3))</code> | Returns a sliding standard of the range of three values returned from the <code>above()</code> function calculated on the current row and the two rows above the current row, as seen in the below table output. |

Example output in table form

| CustID | <code>RangeStdev(SalesValue, 0,3)</code>                                                                                                         |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| 1-20   | -,43.841, 34.192, 18.771, 20.953, 41.138, 47.655, 36.116, 32.716, 25.325, 38,000, 27.737, 35.553, 33.650, 42.532, 33.858, 32.146, 25.239, 35.595 |

#### Data used in examples:

```
SalesTable:
LOAD recno() as CustID, * inline [
SalesValue
101
163
126
139
167
86
83

21
] ;
```

### RangeSum

**RangeSum()** returns the sum of a range of values. All non-numeric values are treated as 0, unlike the + operator.

#### Syntax:

```
RangeSum(first_expr[, Expression])
```

**Return data type:** numeric

#### Arguments:

The argument of this function may contain inter-record functions which in themselves return a list of values.

- `first_expr`: The expression or field containing the data to be summed.
- `Expression`: Optional expressions or fields containing the range of data to be summed. Multiple additional expressions can be used.

#### Limitations:

The **RangeSum** function treats all non-numeric values as 0, unlike the + operator.

### Examples:

Examples and results

| Example             | Result    |
|---------------------|-----------|
| RangeSum (1,2,4)    | Returns 7 |
| RangeSum (5, 'abc') | Returns 5 |
| RangeSum (null( ))  | Returns 0 |

### Example: (using expression)

```
RangeSum (Above(MyField,0,3))
```

Returns the sum of the three values of **MyField**): from the current row and two rows above the current row. By specifying the third argument as 3, the **Above()** function returns three values, where there are sufficient rows above, which are taken as input to the **RangeSum()** function.

*Disable sorting of **MyField** to ensure that example works as expected.*

Example expression output

| MyField | RangeSum(Above(MyField,0,3)) |
|---------|------------------------------|
| 10      | 10                           |
| 2       | 12                           |
| 8       | 20                           |
| 18      | 28                           |
| 5       | 31                           |
| 9       | 32                           |

### Data used in examples:

```
RangeTab:
LOAD * INLINE [
MyField
10
2
8
18
5
9
] ;
```

### Example: (in table form)

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
RangeTab3:
LOAD recno() as RangeID, Rangesum(Field1,Field2,Field3) as MyRangeSum INLINE [
Field1, Field2, Field3
10,5,6
2,3,7
8,2,8
18,11,9
5,5,9
9,4,2
];
```

The resulting table shows the returned values of MyRangeSum for each of the records in the table.

Example output in table form

| RangeID | MyRangeSum |
|---------|------------|
| 1       | 21         |
| 2       | 12         |
| 3       | 18         |
| 4       | 38         |
| 5       | 19         |
| 6       | 15         |

### RangeTextCount

**RangeTextCount()** returns the number of text values in an expression or field.

#### Syntax:

```
RangeTextCount (first_expr[, Expression])
```

**Return data type:** integer

#### Arguments:

The argument of this function may contain inter-record functions which in themselves return a list of values.

- **first\_expr:** The expression or field containing the data to be measured.
- **Expression:** Optional expressions or fields containing the range of data to be measured.

### Examples:

Examples and results

| Example                                | Result    |
|----------------------------------------|-----------|
| <code>RangeTextCount (1,2,4)</code>    | Returns 0 |
| <code>RangeTextCount (5, 'abc')</code> | Returns 1 |
| <code>RangeTextCount (null( ))</code>  | Returns 0 |

### Example: (using expression)

```
RangeTextCount (Above(MaxString(MyField),0,3))
```

Returns the number of text values within the three results of the **MaxString(MyField)** function evaluated over the current row and two rows above the current row.

*Disable sorting of **MyField** to ensure that example works as expected.*

Example expression output

| MyField | MaxString(MyField) | RangeTextCount(Above(Sum(MyField),0,3)) |
|---------|--------------------|-----------------------------------------|
| 10      | 10                 | 0                                       |
| abc     | abc                | 1                                       |
| 8       | 8                  | 1                                       |
| def     | def                | 2                                       |
| xyz     | xyz                | 2                                       |
| 9       | 9                  | 2                                       |

### Data used in examples:

```
RangeTab:
LOAD * INLINE [
MyField
10
'abc'
8
null()
'xyz'
9
] ;
```

## RangeXIRR

**RangeXIRR()** returns the internal rate of return for a schedule of cash flows that is not necessarily periodic. To calculate the internal rate of return for a series of periodic cash flows, use the **RangeIRR** function.

Qlik's XIRR functionality (**XIRR()** and **RangeXIRR()** functions) uses the following equation, solving for the Rate value, to determine the correct XIRR value:

$$\text{XNPV}(\text{Rate}, \text{pmt}, \text{date}) = 0$$

The equation is solved using a simplified version of the Newton method.

### Syntax:

```
RangeXIRR(values, dates[, Expression])
```

**Return data type:** numeric

### Arguments:

- **dates:** A payment date or a schedule of payment dates that corresponds to the cash flow payments.
- **values:** A cash flow or a series of cash flows that correspond to a schedule of payments in dates. Each value may be a single value or a range of values as returned by an inter-record function with a third optional parameter. The series of values must contain at least one positive and one negative value.
- **Expression:** Optional expressions or fields containing the range of data to be measured.

### Limitations:

Text values, NULL values and missing values are disregarded.

All payments are discounted based on a 365-day year.

### Example 1:

`RangeXIRR(-2500, '2008-01-01', 2750, '2008-09-01')` returns 0.1532.

### Example 2:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
RangeTab3:
LOAD *,
recno() as RangeID,
RangeXIRR(Field1,Field2,Field3) as RangeXIRR;
LOAD * INLINE [
Field1|Field2|Field3
10|5|-6000
2|NULL|7000
8|'abc'|8000
18|11|9000
5|5|9000
9|4|2000
] (delimiter is '|');
```

The resulting table shows the returned values of RangeXIRR for each of the records in the table:

Example results

| RangeID | RangeXIRR |
|---------|-----------|
| 1       | -         |
| 2       | 0.5893    |
| 3       | 0.5089    |
| 4       | 0.4476    |
| 5       | 0.4476    |
| 6       | 2.5886    |

### RangeXNPV

**RangeXNPV()** returns the net present value for a schedule of cash flows that is not necessarily periodic. The result has a default number format of money. To calculate the net present value for a series of periodic cash flows, use the **RangeNPV** function.

#### Syntax:

```
RangeXNPV(discount_rate, values, dates[, Expression])
```

**Return data type:** numeric

#### Arguments:

- **dates:** A payment date or a schedule of payment dates that corresponds to the cash flow payments.
- **discount\_rate:** The interest rate per period.
- **values:** A cash flow or a series of cash flows that corresponds to a schedule of payments in dates. Each value may be a single value or a range of values as returned by an inter-record function with a third optional parameter. The series of values must contain at least one positive and one negative value.

#### Limitations:

Text values, NULL values and missing values are disregarded.

All payments are discounted based on a 365-day year.

#### Example 1:

`RangeXNPV(0.1, -2500, '2008-01-01', 2750, '2008-09-01')` returns 80.25.

#### Example 2:

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
RangeTab3:
LOAD *,
```

```
recno() as RangeID,
RangeXNPV(Field1,Field2,Field3) as RangeNPV;
LOAD * INLINE [
Field1|Field2|Field3
10|5|-6000
2|NULL|7000
8|'abc'|8000
18|11|9000
5|5|9000
9|4|2000
] (delimiter is '|');
```

The resulting table shows the returned values of RangeXNPV for each of the records in the table:

Example results

| RangeID | RangeXNPV |
|---------|-----------|
| 1       | \$-49.13  |
| 2       | \$777.78  |
| 3       | \$98.77   |
| 4       | \$25.51   |
| 5       | \$250.83  |
| 6       | \$20.40   |

### NumAvg

Returns the numeric average of 1 to **N** arguments. If no numeric value is found, NULL is returned.

*The numavg function has been superseded by the RangeAvg (page 1480) function. Although numavg can be used, it is not recommended.*

#### Syntax:

```
NumAvg(expr1 [, expr2, ... exprN])
```

#### Examples and results:

- numavg( 1,2,4 ) returns 2.33333333
- numavg( 1,'xyz' ) returns 1
- numavg( null( ) 'abc' ) returns NULL

### NumCount

Returns the number of numeric values found in 1 to **N** arguments.

*The numcount function has been superseded by the RangeCount (page 1483) function. Although numcount can be used, it is not recommended.*

### Syntax:

```
NumCount(expr1 [, expr2, ... exprN])
```

### Examples and results:

- numcount( 1,2,4, ) returns 3
- numcount( 2,xyz ) returns 1
- numcount( null( ) ) returns 0

## NumMax

Returns the highest numeric value of 1 to **N** arguments. If no numeric value is found, NULL is returned.

*The nummax function has been superseded by the RangeMax (page 1489) function. Although nummax can be used, it is not recommended.*

### Syntax:

```
NumMax(expr1 [, expr2, ... exprN])
```

### Examples and results:

- nummax( 1,2,4 ) returns 4
- nummax( 1,'xyz' ) returns 1
- nummax( null( ) 'abc' ) returns NULL

## NumMin

Returns the lowest numeric value of 1 to **N** arguments. If no numeric value is found, NULL is returned.

*The nummin function has been superseded by the RangeMin (page 1492) function. Although nummin can be used, it is not recommended.*

### Syntax:

```
NumMin(expr1 [, expr2, ... exprN])
```

### Examples and results:

- nummin( 1,2,4 ) returns 1
- nummin( 1,'xyz' ) returns 1
- nummin( null( ) 'abc' ) returns NULL

## NumSum

Returns the numeric sum of 1 to **N** arguments. As opposed to the + operator, **numsum** will treat all non-numeric values as 0.

*The numsum function has been superseded by the RangeSum (page 1505) function. Although numsum can be used, it is not recommended.*

### Syntax:

```
NumSum(expr1 [, expr2, ... exprN])
```

### Examples and results:

- numsum( 1,2,4 ) returns 7
- numsum( 1,'xyz' ) returns 1
- numsum( null( ) ) returns 0

## Relational functions

This is a group of functions that calculate properties of individual dimensional values in a chart, using already aggregated numbers.

The functions are relational in the sense that the function output depends not only on the value of the data point itself, but also on the value's relation to other data points. For example, a rank cannot be calculated without a comparison with other dimensional values.

These functions can only be used in chart expressions. They cannot be used in the load script.

A dimension is needed in the chart, since this defines the other data points needed for the comparison. Consequently, a relational function is not meaningful in a dimensionless chart (for example, a KPI object).

## Ranking functions

*Suppression of zero values is automatically disabled when these functions are used. NULL values are disregarded.*

### Rank

**Rank()** evaluates the rows of the chart in the expression, and for each row, displays the relative position of the value of the dimension evaluated in the expression. When evaluating the expression, the function compares the result with the result of the other rows containing the current column segment and returns the ranking of the current row within the segment.

```
Rank - chart function([TOTAL [<fld {, fld}>]] expr[, mode[, fmt]])
```

### HRank

**HRank()** evaluates the expression, and compares the result with the result of the other columns containing the current row segment of a pivot table. The function then returns the ranking of the current column within the segment.

```
HRank - chart function([TOTAL] expr[, mode[, fmt]])
```

### Clustering functions

#### KMeans2D

**KMeans2D()** evaluates the rows of the chart by applying k-means clustering, and for each chart row displays the cluster id of the cluster this data point has been assigned to. The columns that are used by the clustering algorithm are determined by the parameters `coordinate_1`, and `coordinate_2`, respectively. These are both aggregations. The number of clusters that are created is determined by the `num_clusters` parameter. Data can be optionally normalized by the `norm` parameter.

```
KMeans2D - chart function(num_clusters, coordinate_1, coordinate_2 [, norm])
```

#### KMeansND

**KMeansND()** evaluates the rows of the chart by applying k-means clustering, and for each chart row displays the cluster id of the cluster this data point has been assigned to. The columns that are used by the clustering algorithm are determined by the parameters `coordinate_1`, and `coordinate_2`, etc., up to `n` columns. These are all aggregations. The number of clusters that are created is determined by the `num_clusters` parameter.

```
KMeansND - chart function(num_clusters, num_iter, coordinate_1, coordinate_2
[,coordinate_3 [, ...]])
```

#### KMeansCentroid2D

**KMeansCentroid2D()** evaluates the rows of the chart by applying k-means clustering, and for each chart row displays the desired coordinate of the cluster this data point has been assigned to. The columns that are used by the clustering algorithm are determined by the parameters `coordinate_1`, and `coordinate_2`, respectively. These are both aggregations. The number of clusters that are created is determined by the `num_clusters` parameter. Data can be optionally normalized by the `norm` parameter.

```
KMeansCentroid2D - chart function(num_clusters, coordinate_no, coordinate_1,
coordinate_2 [, norm])
```

#### KMeansCentroidND

**KMeansCentroidND()** evaluates the rows of the chart by applying k-means clustering, and for each chart row displays the desired coordinate of the cluster this data point has been assigned to. The columns that are used by the clustering algorithm are determined by the parameters `coordinate_1`, `coordinate_2`, etc., up to `n` columns. These are all aggregations. The number of clusters that are created is determined by the `num_clusters` parameter.

```
KMeansCentroidND - chart function(num_clusters, num_iter, coordinate_no,
coordinate_1, coordinate_2 [,coordinate_3 [, ...]])
```

### Time series decomposition functions

#### STL\_Trend

**STL\_Trend** is a time series decomposition function. Along with **STL\_Seasonal** and **STL\_Residual**, this function is used to decompose a time series into seasonal, trend, and residual components. In the context of the STL algorithm, time series decomposition is used to identify both a recurring seasonal pattern and a

general trend, given an input metric and other parameters. The **STL\_Trend** function will identify a general trend, independent of seasonal patterns or cycles, from time series data.

```
STL_Trend - chart function(target_measure, period_int [,seasonal_smoother
[,trend_smoother]])
```

### STL\_Seasonal

**STL\_Seasonal** is a time series decomposition function. Along with **STL\_Trend** and **STL\_Residual**, this function is used to decompose a time series into seasonal, trend, and residual components. In the context of the STL algorithm, time series decomposition is used to identify both a recurring seasonal pattern and a general trend, given an input metric and other parameters. The **STL\_Seasonal** function can identify a seasonal pattern within a time series, separating this from the general trend displayed by the data.

```
STL_Seasonal - chart function(target_measure, period_int [,seasonal_smoother
[,trend_smoother]])
```

### STL\_Residual

**STL\_Residual** is a time series decomposition function. Along with **STL\_Seasonal** and **STL\_Trend**, this function is used to decompose a time series into seasonal, trend, and residual components. In the context of the STL algorithm, time series decomposition is used to identify both a recurring seasonal pattern and a general trend, given an input metric and other parameters. In performing this operation, part of the variation in the input metric will neither fit within the seasonal nor the trend component, and will be defined as the residual component. The **STL\_Residual** chart function captures this portion of the calculation.

```
STL_Residual - chart function(target_measure, period_int [,seasonal_smoother
[,trend_smoother]])
```

## Rank - chart function

**Rank()** evaluates the rows of the chart in the expression, and for each row, displays the relative position of the value of the dimension evaluated in the expression. When evaluating the expression, the function compares the result with the result of the other rows containing the current column segment and returns the ranking of the current row within the segment.

For charts other than tables, the current column segment is defined as it appears in the chart's straight table equivalent.

### Syntax:

```
Rank ([TOTAL expr[, mode[, fmt]])
```

**Return data type:** dual

### Arguments:

- **expr:** The expression or field containing the data to be measured.
- **mode:** Specifies the number representation of the function result.
- **fmt:** Specifies the text representation of the function result.
- **TOTAL:** If the chart is one-dimensional, or if the expression is preceded by the **TOTAL** qualifier, the function is evaluated across the entire column. If the table or table equivalent has multiple vertical

dimensions, the current column segment will include only rows with the same values as the current row in all dimension columns except for the column showing the last dimension in the inter-field sort order.

The ranking is returned as a dual value, which in the case when each row has a unique ranking, is an integer between 1 and the number of rows in the current column segment.

In the case where several rows share the same ranking, the text and number representation can be controlled with the **mode** and **fmt** parameters.

### mode

The second argument, **mode**, can take the following values:

Second argument values

| Value       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (default) | If all ranks within the sharing group fall on the low side of the middle value of the entire ranking, all rows get the lowest rank within the sharing group.<br><br>If all ranks within the sharing group fall on the high side of the middle value of the entire ranking, all rows get the highest rank within the sharing group.<br><br>If ranks within the sharing group span over the middle value of the entire ranking, all rows get the value corresponding to the average of the top and bottom ranking in the entire column segment. |
| 1           | Lowest rank on all rows.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 2           | Average rank on all rows.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 3           | Highest rank on all rows.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 4           | Lowest rank on first row, then incremented by one for each row.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### fmt

The third argument, **fmt**, can take the following values:

Third argument values

| Value       | Description                                             |
|-------------|---------------------------------------------------------|
| 0 (default) | Low value - high value on all rows (for example 3 - 4). |
| 1           | Low value on all rows.                                  |
| 2           | Low value on first row, blank on the following rows.    |

The order of rows for **mode** 4 and **fmt** 2 is determined by the sort order of the chart dimensions.

### Examples and results:

Create two charts from the dimensions Product and Sales and another from Product and UnitSales. Add measures as shown in the following table.

### Example 1:

Create a table with the dimensions `Customer` and `Sales` and the measure `Rank(Sales)`.

The result depends on the sort order of the dimensions. If the table is sorted on `Customer`, the table lists all the values of `Sales` for `Astrida`, then `Betacab`, and so on. The results for `Rank(Sales)` will show 10 for the `Sales` value 12, 9 for the `Sales` value 13, and so on, with the rank value of 1 returned for the `Sales` value 78. The next column segment begins with `Betacab`, for which the first value of `Sales` in the segment is 12. The rank value of `Rank(Sales)` for this is given as 11.

If the table is sorted on `Sales`, the column segments consist of the values of `Sales` and the corresponding `Customer`. Because there are two `Sales` values of 12 (for `Astrida` and `Betacab`), the value of `Rank(Sales)` for that column segment is 1-2, for each value of `Customer`. This is because there are two values of `Customer` for the `Sales` value 12. If there had been 4 values, the result would be 1-4, for all rows. This shows what the result looks like for the default value (0) of the argument `fmt`.

### Example 2:

Replace the dimension `Customer` with `Product` and add the measure `Rank(Sales, 1, 2)`.

This returns 1 on the first row on each column segment and leaves all other rows blank, because arguments `mode` and `fmt` are set to 1 and 2 respectively.

### Data used in examples:

`ProductData:`

```
Load * inline [
Customer|Product|UnitsSales|UnitPrice
Astrida|AA|4|16
Astrida|AA|10|15
Astrida|BB|9|9
Betacab|BB|5|10
Betacab|CC|2|20
Betacab|DD|0|25
Canutility|AA|8|15
Canutility|CC|0|19
] (delimiter is '|');
```

`Sales2013:`

```
crosstable (Month, Sales) LOAD * inline [
Customer|Jan|Feb|Mar|Apr|May|Jun|Jul|Aug|Sep|Oct|Nov|Dec
Astrida|46|60|70|13|78|20|45|65|78|12|78|22
Betacab|65|56|22|79|12|56|45|24|32|78|55|15
Canutility|77|68|34|91|24|68|57|36|44|90|67|27
Divadip|57|36|44|90|67|27|57|68|47|90|80|94
] (delimiter is '|');
```

### HRank - chart function

**HRank()** evaluates the expression, and compares the result with the result of the other columns containing the current row segment of a pivot table. The function then returns the ranking of the current column within the segment.

#### Syntax:

```
HRank([total] expression [, mode [, format]])
```

**Return data type:** dual

*This function only works in pivot tables. In all other chart types it returns NULL.*

#### Arguments:

- **expression:** The expression or field containing the data to be measured.
- **mode:** Specifies the number representation of the function result.
- **format:** Specifies the text representation of the function result.
- **TOTAL:** If the word **TOTAL** occurs before the function arguments, the calculation is made over all possible values given the current selections, and not just those that pertain to the current dimensional value, that is, it disregards the chart dimensions. The **TOTAL** qualifier may be followed by a list of one or more field names within angle brackets <fld>. These field names should be a subset of the chart dimension variables.

If the pivot table is one-dimensional or if the expression is preceded by the **total** qualifier, the current row segment is always equal to the entire row. If the pivot table has multiple horizontal dimensions, the current row segment will include only columns with the same values as the current column in all dimension rows except for the row showing the last horizontal dimension of the inter-field sort order.

The ranking is returned as a dual value, which in the case when each column has a unique ranking will be an integer between 1 and the number of columns in the current row segment.

In the case where several columns share the same ranking, the text and number representation can be controlled with the **mode** and **format** arguments.

The second argument, **mode**, specifies the number representation of the function result:

Second argument values

| Value       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (default) | If all ranks within the sharing group fall on the low side of the middle value of the entire ranking, all columns get the lowest rank within the sharing group.<br>If all ranks within the sharing group fall on the high side of the middle value of the entire ranking, all columns get the highest rank within the sharing group.<br>If ranks within the sharing group span over the middle value of the entire ranking, all rows get the value corresponding to the average of the top and bottom ranking in the entire column segment. |
| 1           | Lowest rank on all columns in the group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 2           | Average rank on all columns in the group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 3           | Highest rank on all columns in the group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 4           | Lowest rank on first column, then incremented by one for each column in the group.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

The third argument, **format**, specifies the text representation of the function result:

Third argument values

| Value       | Description                                                                 |
|-------------|-----------------------------------------------------------------------------|
| 0 (default) | Low value&' - '&high value on all columns in the group (for example 3 - 4). |
| 1           | Low value on all columns in the group.                                      |
| 2           | Low value on first column, blank on the following columns in the group.     |

The order of columns for **mode** 4 and **format** 2 is determined by the sort order of the chart dimensions.

### Examples:

```
HRank(sum(sales))
HRank(sum(sales), 2)
HRank(sum(sales), 0, 1)
```

### VRank - chart function

**VRank()** performs the same function as **Rank** function. You may use either.

#### Syntax:

```
VRank ([TOTAL [<fld {, fld}>]] expr[, mode[, fmt]])
```

**Return data type:** dual

### KMeans2D - chart function

**KMeans2D()** evaluates the rows of the chart by applying k-means clustering, and for each chart row displays the cluster id of the cluster this data point has been assigned to. The columns that are used by the

clustering algorithm are determined by the parameters `coordinate_1`, and `coordinate_2`, respectively. These are both aggregations. The number of clusters that are created is determined by the `num_clusters` parameter. Data can be optionally normalized by the `norm` parameter.

**KMeans2D** returns one value per data point. The returned value is a dual and is the integer value corresponding to the cluster each data point has been assigned to.

### Syntax:

```
KMeans2D (num_clusters, coordinate_1, coordinate_2 [, norm])
```

**Return data type:** dual

### Arguments:

#### Arguments

| Argument                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>num_clusters</code> | Integer that specifies the number of clusters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>coordinate_1</code> | The aggregation that calculates the first coordinate, usually the x-axis of the scatter chart that can be made from the chart. The additional parameter, <code>coordinate_2</code> , calculates the second coordinate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>norm</code>         | <p>The optional normalization method applied to datasets before KMeans clustering.</p> <p>Possible values:</p> <ul style="list-style-type: none"><li>0 or 'none' for no normalization</li><li>1 or 'zscore' for z-score normalization</li><li>2 or 'minmax' for min-max normalization</li></ul> <p>If no parameter is supplied or if the supplied parameter is incorrect, no normalization is applied.</p> <p>Z-score normalizes data based on feature mean and standard deviation. Z-score does not ensure each feature has the same scale but it is a better approach than min-max when dealing with outliers.</p> <p>Min-max normalization ensures that the features have the same scale by taking the minimum and maximum values of each and recalculating each datapoint.</p> |

### Auto-clustering

**KMeans** functions support auto-clustering using a method called depth difference (DeD). When a user sets 0 for the number of clusters, an optimal number of clusters for that dataset is determined. Note that while an integer for the number of clusters (*k*) is not explicitly returned, it is calculated within the KMeans algorithm. For example, if 0 is specified in the function for the value of *KmeansPetalClusters* or set through a variable input box, cluster assignments are automatically calculated for the dataset based on an optimal number of clusters.

### KMeansND - chart function

**KMeansND()** evaluates the rows of the chart by applying k-means clustering, and for each chart row displays the cluster id of the cluster this data point has been assigned to. The columns that are used by the clustering algorithm are determined by the parameters `coordinate_1`, and `coordinate_2`, etc., up to `n` columns. These are all aggregations. The number of clusters that are created is determined by the `num_clusters` parameter.

**KMeansND** returns one value per data point. The returned value is a dual and is the integer value corresponding to the cluster each data point has been assigned to.

#### Syntax:

```
KMeansND(num_clusters, num_iter, coordinate_1, coordinate_2 [,coordinate_3 [, ...]])
```

**Return data type:** dual

#### Arguments:

##### Arguments

| Argument                  | Description                                                                                                                                                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>num_clusters</code> | Integer that specifies the number of clusters.                                                                                                                                                                     |
| <code>num_iter</code>     | The number of iterations of clustering with reinitialized cluster centers.                                                                                                                                         |
| <code>coordinate_1</code> | The aggregation that calculates the first coordinate, usually the x-axis (of a scatter chart that can be made from the chart). The additional parameters calculate the second, third, and fourth coordinates, etc. |

#### Auto-clustering

**KMeans** functions support auto-clustering using a method called depth difference (DeD). When a user sets 0 for the number of clusters, an optimal number of clusters for that dataset is determined. Note that while an integer for the number of clusters ( $k$ ) is not explicitly returned, it is calculated within the KMeans algorithm. For example, if 0 is specified in the function for the value of *KmeansPetalClusters* or set through a variable input box, cluster assignments are automatically calculated for the dataset based on an optimal number of clusters.

### KMeansCentroid2D - chart function

**KMeansCentroid2D()** evaluates the rows of the chart by applying k-means clustering, and for each chart row displays the desired coordinate of the cluster this data point has been assigned to. The columns that are used by the clustering algorithm are determined by the parameters `coordinate_1`, and `coordinate_2`, respectively. These are both aggregations. The number of clusters that are created is determined by the `num_clusters` parameter. Data can be optionally normalized by the `norm` parameter.

**KMeansCentroid2D** returns one value per data point. The returned value is a dual and is one of the coordinates of the position corresponding to the cluster center the data point has been assigned to.

### Syntax:

```
KMeansCentroid2D(num_clusters, coordinate_no, coordinate_1, coordinate_2 [, norm])
```

**Return data type:** dual

### Arguments:

#### Arguments

| Argument      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| num_clusters  | Integer that specifies the number of clusters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| coordinate_no | The desired coordinate number of the centroids (corresponding, for example, to the x, y, or z axis).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| coordinate_1  | The aggregation that calculates the first coordinate, usually the x-axis of the scatter chart that can be made from the chart. The additional parameter, coordinate_2, calculates the second coordinate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| norm          | <p>The optional normalization method applied to datasets before KMeans clustering.</p> <p>Possible values:</p> <ul style="list-style-type: none"> <li>0 or 'none' for no normalization</li> <li>1 or 'zscore' for z-score normalization</li> <li>2 or 'minmax' for min-max normalization</li> </ul> <p>If no parameter is supplied or if the supplied parameter is incorrect, no normalization is applied.</p> <p>Z-score normalizes data based on feature mean and standard deviation. Z-score does not ensure each feature has the same scale but it is a better approach than min-max when dealing with outliers.</p> <p>Min-max normalization ensures that the features have the same scale by taking the minimum and maximum values of each and recalculating each datapoint.</p> |

### Auto-clustering

**KMeans** functions support auto-clustering using a method called depth difference (DeD). When a user sets 0 for the number of clusters, an optimal number of clusters for that dataset is determined. Note that while an integer for the number of clusters ( $k$ ) is not explicitly returned, it is calculated within the KMeans algorithm. For example, if 0 is specified in the function for the value of *KmeansPetalClusters* or set through a variable input box, cluster assignments are automatically calculated for the dataset based on an optimal number of clusters.

### KMeansCentroidND - chart function

**KMeansCentroidND()** evaluates the rows of the chart by applying k-means clustering, and for each chart row displays the desired coordinate of the cluster this data point has been assigned to. The columns that are used by the clustering algorithm are determined by the parameters `coordinate_1`, `coordinate_2`, etc., up to `n` columns. These are all aggregations. The number of clusters that are created is determined by the `num_clusters` parameter.

**KMeansCentroidND** returns one value per row. The returned value is a dual and is one of the coordinates of the position corresponding to the cluster center the data point has been assigned to.

#### Syntax:

```
KMeansCentroidND(num_clusters, num_iter, coordinate_no, coordinate_1,
coordinate_2 [,coordinate_3 [, ...]])
```

**Return data type:** dual

#### Arguments:

##### Arguments

| Argument                   | Description                                                                                                                                                                                                        |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>num_clusters</code>  | Integer that specifies the number of clusters.                                                                                                                                                                     |
| <code>num_iter</code>      | The number of iterations of clustering with reinitialized cluster centers.                                                                                                                                         |
| <code>coordinate_no</code> | The desired coordinate number of the centroids (corresponding, for example, to the x, y, or z axis).                                                                                                               |
| <code>coordinate_1</code>  | The aggregation that calculates the first coordinate, usually the x-axis (of a scatter chart that can be made from the chart). The additional parameters calculate the second, third, and fourth coordinates, etc. |

#### Auto-clustering

**KMeans** functions support auto-clustering using a method called depth difference (DeD). When a user sets 0 for the number of clusters, an optimal number of clusters for that dataset is determined. Note that while an integer for the number of clusters (*k*) is not explicitly returned, it is calculated within the KMeans algorithm. For example, if 0 is specified in the function for the value of *KmeansPetalClusters* or set through a variable input box, cluster assignments are automatically calculated for the dataset based on an optimal number of clusters.

### STL\_Trend - chart function

**STL\_Trend** is a time series decomposition function. Along with **STL\_Seasonal** and **STL\_Residual**, this function is used to decompose a time series into seasonal, trend, and residual components. In the context of the STL algorithm, time series decomposition is used to identify both a recurring seasonal pattern and a general trend, given an input metric and other parameters. The **STL\_Trend** function will identify a general trend, independent of seasonal patterns or cycles, from time series data.

The three STL functions are related to the input metric through a simple sum:

**STL\_Trend + STL\_Seasonal + STL\_Residual = Input metric**

STL (seasonal and trend decomposition using Loess) employs data smoothing techniques, and through its input parameters, allows the user to adjust the periodicity of the calculations it performs. This periodicity determines how the time dimension of the input metric (a measure) is segmented in the analysis.

At minimum, **STL\_Trend** takes an input metric (*target\_measure*) and an integer value for its *period\_int*, returning a floating-point value. The input metric will be in the form of an aggregation that varies along the time dimension. Optionally, you can include values for the *seasonal\_smoother* and *trend\_smoother* to adjust the smoothing algorithm.

### Syntax:

```
STL_Trend(target_measure, period_int [,seasonal_smoother [,trend_smoother]])
```

**Return data type:** dual

### Arguments

| Argument                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>target_measure</b>    | The measure to decompose into Seasonal and Trend components. This should be a measure such as Sum(Sales) or Sum(Passengers) that varies along the time dimension.<br><br>This must not be a constant value.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>period_int</b>        | The periodicity of the dataset. This parameter is an integer value representing the number of discrete steps that make up one period, or seasonal cycle, of the signal.<br><br>For instance, if the time series is segmented into one section for each quarter of the year, you must set the <b>period_int</b> to a value of 4 to define the periodicity as Year.                                                                                                                                                                                                                                                                                                        |
| <b>seasonal_smoother</b> | Length of the seasonal smoother. This must be an odd integer. The seasonal smoother uses data for a particular phase in the seasonal variation, over a number of periods. One discrete step of the time dimension is used from each period. The seasonal smoother indicates the number of periods used for smoothing.<br><br>For example, if the time dimension is segmented by month and the period is Year (12), the seasonal component will be computed so that each particular month of each year is calculated from data for the same month, both in that year and in adjacent years. The <b>seasonal_smoother</b> value is the number of years used for smoothing. |
| <b>trend_smoother</b>    | Length of the trend smoother. This must be an odd integer. The trend smoother uses the same time scale as the <b>period_int</b> parameter, and its value is the number of granules used for smoothing.<br><br>For example, if a time series is segmented by month, the trend smoother will be the number of months used for smoothing.                                                                                                                                                                                                                                                                                                                                   |

The **STL\_Trend** chart function is often used in combination with the following functions:

### Related functions

|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>STL_Seasonal - chart function (page 1525)</i> | This is the function used to compute the seasonal component of a time series.                                                                                                                                                             |
| <i>STL_Residual - chart function (page 1527)</i> | When breaking down an input metric into seasonal and trend component, part of the measure's variation will not fit within either of the two main components. The <b>STL_Residual</b> function computes this portion of the decomposition. |

### STL\_Seasonal - chart function

**STL\_Seasonal** is a time series decomposition function. Along with **STL\_Trend** and **STL\_Residual**, this function is used to decompose a time series into seasonal, trend, and residual components. In the context of the STL algorithm, time series decomposition is used to identify both a recurring seasonal pattern and a general trend, given an input metric and other parameters. The **STL\_Seasonal** function can identify a seasonal pattern within a time series, separating this from the general trend displayed by the data.

The three STL functions are related to the input metric through a simple sum:

**STL\_Trend + STL\_Seasonal + STL\_Residual = Input metric**

STL (seasonal and trend decomposition using Loess) employs data smoothing techniques, and through its input parameters, allows the user to adjust the periodicity of the calculations it performs. This periodicity determines how the time dimension of the input metric (a measure) is segmented in the analysis.

At minimum, **STL\_Seasonal** takes an input metric (`target_measure`) and an integer value for its `period_int`, returning a floating-point value. The input metric will be in the form of an aggregation that varies along the time dimension. Optionally, you can include values for the `seasonal_smoother` and `trend_smoother` to adjust the smoothing algorithm.

### Syntax:

```
STL_Seasonal(target_measure, period_int [,seasonal_smoother [,trend_smoother]])
```

**Return data type:** dual

### Arguments

| Argument                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>target_measure</b>    | <p>The measure to decompose into Seasonal and Trend components. This should be a measure such as Sum(Sales) or Sum(Passengers) that varies along the time dimension.</p> <p>This must not be a constant value.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>period_int</b>        | <p>The periodicity of the dataset. This parameter is an integer value representing the number of discrete steps that make up one period, or seasonal cycle, of the signal.</p> <p>For instance, if the time series is segmented into one section for each quarter of the year, you must set the <b>period_int</b> to a value of 4 to define the periodicity as Year.</p>                                                                                                                                                                                                                                                                                                        |
| <b>seasonal_smoother</b> | <p>Length of the seasonal smoother. This must be an odd integer. The seasonal smoother uses data for a particular phase in the seasonal variation, over a number of periods. One discrete step of the time dimension is used from each period. The seasonal smoother indicates the number of periods used for smoothing.</p> <p>For example, if the time dimension is segmented by month and the period is Year (12), the seasonal component will be computed so that each particular month of each year is calculated from data for the same month, both in that year and in adjacent years. The <b>seasonal_smoother</b> value is the number of years used for smoothing.</p> |
| <b>trend_smoother</b>    | <p>Length of the trend smoother. This must be an odd integer. The trend smoother uses the same time scale as the <b>period_int</b> parameter, and its value is the number of granules used for smoothing.</p> <p>For example, if a time series is segmented by month, the trend smoother will be the number of months used for smoothing.</p>                                                                                                                                                                                                                                                                                                                                   |

The **STL\_Seasonal** chart function is often used in combination with the following functions:

| <i>STL_Residual</i> - chart function (page 1527) | When breaking down an input metric into seasonal and trend component, part of the measure's variation will not fit within either of the two main components. The <b>STL_Residual</b> function computes this portion of the decomposition. |

### STL\_Residual - chart function

**STL\_Residual** is a time series decomposition function. Along with **STL\_Seasonal** and **STL\_Trend**, this function is used to decompose a time series into seasonal, trend, and residual components. In the context of the STL algorithm, time series decomposition is used to identify both a recurring seasonal pattern and a general trend, given an input metric and other parameters. In performing this operation, part of the variation in the input metric will neither fit within the seasonal nor the trend component, and will be defined as the residual component. The **STL\_Residual** chart function captures this portion of the calculation.

The three STL functions are related to the input metric through a simple sum:

**STL\_Trend + STL\_Seasonal + STL\_Residual = Input metric**

STL (seasonal and trend decomposition using Loess) employs data smoothing techniques, and through its input parameters, allows the user to adjust the periodicity of the calculations it performs. This periodicity determines how the time dimension of the input metric (a measure) is segmented in the analysis.

Since time series decomposition primarily looks for seasonality and general variations in data, the information in the residual is considered the least significant of the three components. However, a skewed or periodic residual component can help identify issues in the calculation, such as incorrect periodicity settings.

At minimum, **STL\_Residual** takes an input metric (`target_measure`) and an integer value for its `period_int`, returning a floating-point value. The input metric will be in the form of an aggregation that varies along the time dimension. Optionally, you can include values for the `seasonal_smoother` and `trend_smoother` to adjust the smoothing algorithm.

#### Syntax:

```
STL_Residual(target_measure, period_int [,seasonal_smoother [,trend_smoother]])
```

**Return data type:** dual

### Arguments

| Argument                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

### Statistical distribution functions

Statistical distribution functions return the probabilities of occurrence of different possible outcomes for a given input variable. You can use these functions to calculate the potential values of your data points.

The three groups of statistical distribution functions described below are all implemented in Qlik Sense using the Cephес function library. For references and details on algorithms used, accuracy, and so on, see: [≤ Cephес library](#). The Cephес function library is used by permission.

- The probability functions calculate the probability at the point in the distribution given by the supplied value.
  - The Frequency functions are used for discrete distributions.
  - The Density functions are used for continuous functions.
- The Dist functions calculate the accumulated probability of the distribution at the point in the distribution given by the supplied value.
- The Inv functions calculate the inverse value, given the accumulated probability of the distribution.

All functions can be used in both the data load script and in chart expressions.

### Statistical distribution functions overview

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

#### BetaDensity

`betaDensity()` returns the probability of the Beta distribution.

```
BetaDensity (value, alpha, beta)
```

#### BetaDist

`betaDist()` returns the accumulated probability of the Beta distribution.

```
BetaDist (value, alpha, beta)
```

#### BetaInv

`betaINV()` returns the inverse of the accumulated probability of the Beta distribution.

```
BetaInv (prob, alpha, beta)
```

### BinomDist

`BinomDist()` returns the accumulated probability of the Binomial distribution.

```
BinomDist (value, trials, trial_probability)
```

### BinomFrequency

`BinomFrequency()` returns the Binomial probability distribution.

```
BinomFrequency (value, trials, trial_probability)
```

### BinomInv

`BinomInv()` returns the inverse of the accumulated probability of the Binomial distribution.

```
BinomInv (prob, trials, trial_probability)
```

### ChiDensity

`ChiDensity()` returns the one-tailed probability of the  $\chi^2$  distribution. The  $\chi^2$  density function is associated with a  $\chi^2$  test.

```
ChiDensity (value, degrees_freedom)
```

### ChiDist

`ChiDist()` returns the one-tailed probability of the  $\chi^2$  distribution. The  $\chi^2$  distribution is associated with a  $\chi^2$  test.

```
ChiDist (value, degrees_freedom)
```

### ChiInv

`ChiInv()` returns the inverse of the one-tailed probability of the  $\chi^2$  distribution.

```
ChiInv (prob, degrees_freedom)
```

### FDensity

`FDensity()` returns the probability of the F distribution.

```
FDensity (value, degrees_freedom1, degrees_freedom2)
```

### FDist

`FDist()` returns the accumulated probability of the F distribution.

```
FDist (value, degrees_freedom1, degrees_freedom2)
```

### FInv

`FInv()` returns the inverse of the accumulated probability of the F distribution.

```
FInv (prob, degrees_freedom1, degrees_freedom2)
```

### GammaDensity

`GammaDensity()` returns the probability of the Gamma distribution.

```
GammaDensity (value, k, θ)
```

### GammaDist

GammaDist() returns the accumulated probability of the Gamma distribution.

```
GammaDist (value, k, θ)
```

### Gammaln

GammaInv() returns the inverse of the accumulated probability of the Gamma distribution.

```
GammaInv (prob, k, θ)
```

### NormDist

NormDist() returns the cumulative normal distribution for the specified mean and standard deviation. If mean = 0 and standard\_dev = 1, the function returns the standard normal distribution.

```
NormDist (value, mean, standard_dev)
```

### NormInv

NormInv() returns the inverse of the normal cumulative distribution for the specified mean and standard deviation.

```
NormInv (prob, mean, standard_dev)
```

### PoissonDist

PoissonDist() returns the accumulated probability of the Poisson distribution.

```
PoissonDist (value, mean)
```

### PoissonFrequency

PoissonFrequency() returns the Poisson probability distribution.

```
PoissonFrequency (value, mean)
```

### PoissonInv

PoissonInv() returns the inverse of the accumulated probability of the Poisson distribution.

```
PoissonInv (prob, mean)
```

### TDensity

TDensity() returns the value for the student's  $t$  density function where a numeric value is a calculated value of  $t$  for which the probability is to be computed.

```
TDensity (value, degrees_freedom, tails)
```

### TDist

TDist() returns the probability for the student's  $t$  distribution where a numeric value is a calculated value of  $t$  for which the probability is to be computed.

```
TDist (value, degrees_freedom, tails)
```

### TInv

TInv() returns the  $t$  value of the student's  $t$  distribution as a function of the probability and the degrees of freedom.

```
TInv (prob, degrees_freedom)
```

### BetaDensity

BetaDensity() returns the probability of the Beta distribution.

#### Syntax:

```
BetaDensity(value, alpha, beta)
```

**Return data type:** number

#### Arguments

| Argument | Description                                                                                                    |
|----------|----------------------------------------------------------------------------------------------------------------|
| value    | The value at which you want to evaluate the distribution. The value must be between 0 and 1.                   |
| alpha    | A positive number defining the first shape parameter. It is the exponent of the random variable                |
| beta     | A positive number defining the second shape parameter. It states the number of denominator degrees of freedom. |

### BetaDist

BetaDist() returns the accumulated probability of the Beta distribution.

#### Syntax:

```
BetaDist(value, alpha, beta)
```

**Return data type:** number

#### Arguments

| Argument | Description                                                                                                            |
|----------|------------------------------------------------------------------------------------------------------------------------|
| value    | The value at which you want to evaluate the distribution. The value must be between 0 and 1.                           |
| alpha    | A positive number defining the first shape parameter. It is the exponent of the random variable                        |
| beta     | A positive number defining the second shape parameter. It is the exponent that controls the shape of the distribution. |

This function is related to the BetaInv function in the following way:

If  $prob = \text{BetaDist}(value, alpha, beta)$ , then  $\text{BetaInv}(prob, alpha, beta) = value$

### BetaInv

`BetaInv()` returns the inverse of the accumulated probability of the Beta distribution.

#### Syntax:

```
BetaInv(prob, alpha, beta)
```

**Return data type:** number

#### Arguments

| Argument | Description                                                                                                            |
|----------|------------------------------------------------------------------------------------------------------------------------|
| prob     | A probability associated with the Beta-probability distribution. It must be a number between 0 and 1.                  |
| alpha    | A positive number defining the first shape parameter. It is the exponent of the random variable                        |
| beta     | A positive number defining the second shape parameter. It is the exponent that controls the shape of the distribution. |

This function is related to the `BetaDist` function in the following way:

If `prob = BetaDist(value, alpha, beta)`, then `BetaInv(prob, alpha, beta) = value`

### BinomDist

`BinomDist()` returns the accumulated probability of the Binomial distribution.

#### Syntax:

```
BinomDist(value, trials, trial_probability)
```

**Return data type:** number

#### Arguments

| Argument          | Description                                                                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| value             | The value at which you want to evaluate the distribution. The value must be an integer not smaller than zero and not greater than the number of trials. |
| trials            | A positive integer that states the number of trials.                                                                                                    |
| trial_probability | The success probability for each trial. It is always a number between 0 and 1.                                                                          |

This function is related to the `BinomInv` function in the following way:

If `prob = BinomDist(value, trials, trial_probability)`, then `BinomInv(prob, trials, trial_probability) = value`

### BinomFrequency

`BinomFrequency()` returns the Binomial probability distribution.

**Syntax:**

```
BinomFrequency(value, trials, trial_probability)
```

**Return data type:** number

### Arguments

| Argument          | Description                                                                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| value             | The value at which you want to evaluate the distribution. The value must be an integer not smaller than zero and not greater than the number of trials. |
| trials            | A positive integer that states the number of trials                                                                                                     |
| trial_probability | The success probability for each trial. It is always a number between 0 and 1.                                                                          |

## BinomInv

`BinomInv()` returns the inverse of the accumulated probability of the Binomial distribution.

**Syntax:**

```
BinomInv(prob, trials, trial_probability)
```

**Return data type:** number

### Arguments

| Argument          | Description                                                                                               |
|-------------------|-----------------------------------------------------------------------------------------------------------|
| prob              | A probability associated with the Binomial-probability distribution. It must be a number between 0 and 1. |
| trials            | A positive integer that states the number of trials.                                                      |
| trial_probability | The success probability for each trial. It is always a number between 0 and 1.                            |

This function is related to the `BinomDist` function in the following way:

If `prob = BinomDist(value, trials, trial_probability)`, then `BinomInv(prob, trials, trial_probability) = value`

## ChiDensity

`ChiDensity()` returns the one-tailed probability of the  $\chi^2$  distribution. The  $\chi^2$  density function is associated with a  $\chi^2$  test.

**Syntax:**

```
ChiDensity(value, degrees_freedom)
```

**Return data type:** number

### Arguments

| Argument        | Description                                                                               |
|-----------------|-------------------------------------------------------------------------------------------|
| value           | The value at which you want to evaluate the distribution. The value must not be negative. |
| degrees_freedom | A positive integer stating the number of numerator degrees of freedom.                    |

## ChiDist

**ChiDist()** returns the one-tailed probability of the  $\chi^2$  distribution. The  $\chi^2$  distribution is associated with a  $\chi^2$  test.

### Syntax:

```
ChiDist(value, degrees_freedom)
```

**Return data type:** number

### Arguments:

#### CHIDIST arguments

| Argument        | Description                                                                               |
|-----------------|-------------------------------------------------------------------------------------------|
| value           | The value at which you want to evaluate the distribution. The value must not be negative. |
| degrees_freedom | A positive integer stating the number of degrees of freedom.                              |

This function is related to the **ChiInv** function in the following way:  
If  $\text{prob} = \text{ChiDist}(\text{value}, \text{df})$ , then  $\text{ChiInv}(\text{prob}, \text{df}) = \text{value}$

### Limitations:

All arguments must be numeric, else NULL will be returned.

### Examples and results:

#### Examples and results

| Example         | Result         |
|-----------------|----------------|
| CHIDIST( 8, 15) | Returns 0.9238 |

## ChiInv

**ChiInv()** returns the inverse of the one-tailed probability of the  $\chi^2$  distribution.

### Syntax:

```
ChiInv(prob, degrees_freedom)
```

**Return data type:** number

### Arguments:

#### CHIINV arguments

| Argument        | Description                                                                                           |
|-----------------|-------------------------------------------------------------------------------------------------------|
| prob            | A probability associated with the chi <sup>2</sup> distribution. It must be a number between 0 and 1. |
| degrees_freedom | An integer stating the number of degrees of freedom.                                                  |

This function is related to the **ChiDist** function in the following way:

If  $prob = ChiDist(value, df)$ , then  $ChiInv(prob, df) = value$

### Limitations:

All arguments must be numeric, else NULL will be returned.

### Examples and results:

#### Examples and results

| Example               | Result         |
|-----------------------|----------------|
| ChiInv(0.9237827, 15) | Returns 8.0000 |

## FDensity

`FDensity()` returns the probability of the F distribution.

### Syntax:

```
FDensity(value, degrees_freedom1, degrees_freedom2)
```

**Return data type:** number

#### Arguments

| Argument         | Description                                                                               |
|------------------|-------------------------------------------------------------------------------------------|
| value            | The value at which you want to evaluate the distribution. The value must not be negative. |
| degrees_freedom1 | A positive integer stating the number of numerator degrees of freedom.                    |
| degrees_freedom2 | A positive integer stating the number of denominator degrees of freedom.                  |

### FDist

**FDist()** returns the F-probability distribution.

**Syntax:**

```
FDist(value, degrees_freedom1, degrees_freedom2)
```

**Return data type:** number

**Arguments:**

FDIST arguments

| Argument         | Description                                                                                  |
|------------------|----------------------------------------------------------------------------------------------|
| value            | The value at which you want to evaluate the distribution. <b>Value</b> must not be negative. |
| degrees_freedom1 | A positive integer stating the number of numerator degrees of freedom.                       |
| degrees_freedom2 | A positive integer stating the number of denominator degrees of freedom.                     |

This function is related to the **FInv** function in the following way:

If  $\text{prob} = \text{FDist}(\text{value}, \text{df1}, \text{df2})$ , then  $\text{FInv}(\text{prob}, \text{df1}, \text{df2}) = \text{value}$

**Limitations:**

All arguments must be numeric, else NULL will be returned.

**Examples and results:**

Examples and results

| Example         | Result         |
|-----------------|----------------|
| FDist(15, 8, 6) | Returns 0.0019 |

### FInv

**FInv()** returns the inverse of the F-probability distribution.

**Syntax:**

```
FInv(prob, degrees_freedom1, degrees_freedom2)
```

**Return data type:** number

**Arguments:**

FINV arguments

| Argument        | Description                                                                                        |
|-----------------|----------------------------------------------------------------------------------------------------|
| prob            | A probability associated with the F-probability distribution and must be a number between 0 and 1. |
| degrees_freedom | An integer stating the number of degrees of freedom.                                               |

This function is related to the **FDist** function in the following way:

If  $\text{prob} = \text{FDist}(\text{value}, \text{df1}, \text{df2})$ , then  $\text{FInv}(\text{prob}, \text{df1}, \text{df2}) = \text{value}$

**Limitations:**

All arguments must be numeric, else NULL will be returned.

**Examples and results:**

Examples and results

| Example                             | Result          |
|-------------------------------------|-----------------|
| <code>FInv( 0.0019369, 8, 6)</code> | Returns 15.0000 |

### GammaDensity

`GammaDensity()` returns the probability of the Gamma distribution.

**Syntax:**

```
GammaDensity(value, k, θ)
```

**Return data type:** number

Arguments

| Argument | Description                                                                               |
|----------|-------------------------------------------------------------------------------------------|
| value    | The value at which you want to evaluate the distribution. The value must not be negative. |
| k        | A positive number defining the shape parameter.                                           |
| $\theta$ | A positive number defining the scale parameter.                                           |

### GammaDist

`GammaDist()` returns the accumulated probability of the Gamma distribution.

**Syntax:**

```
GammaDist(value, k, θ)
```

**Return data type:** number

### Arguments

| Argument | Description                                                                               |
|----------|-------------------------------------------------------------------------------------------|
| value    | The value at which you want to evaluate the distribution. The value must not be negative. |
| k        | A positive number defining the shape parameter.                                           |
| $\theta$ | A positive number defining the scale parameter.                                           |

This function is related to the `GammaInv` function in the following way:

If `prob = GammaDist(value, k,  $\theta$ )`, then `GammaInv(prob, k,  $\theta$ ) = value`

## GammaInv

`GammaInv()` returns the inverse of the accumulated probability of the Gamma distribution.

**Syntax:**

```
GammaInv(prob, k, θ)
```

**Return data type:** number

### Arguments

| Argument | Description                                                                                            |
|----------|--------------------------------------------------------------------------------------------------------|
| prob     | A probability associated with the Gamma-probability distribution. It must be a number between 0 and 1. |
| k        | A positive number defining the shape parameter.                                                        |
| $\theta$ | A positive number defining the scale parameter.                                                        |

This function is related to the `GammaDist` function in the following way:

If `prob = GammaDist(value, k,  $\theta$ )`, then `GammaInv(prob, k,  $\theta$ ) = value`

## NormDist

**NormDist()** returns the cumulative normal distribution for the specified mean and standard deviation. If `mean = 0` and `standard_dev = 1`, the function returns the standard normal distribution.

**Syntax:**

```
NormDist(value, mean, standard_dev)
```

**Return data type:** number

**Arguments:**

NORMDIST arguments

| Argument     | Description                                                          |
|--------------|----------------------------------------------------------------------|
| value        | The value at which you want to evaluate the distribution.            |
| mean         | A value stating the arithmetic mean for the distribution.            |
| standard_dev | A positive value stating the standard deviation of the distribution. |

This function is related to the **NormInv** function in the following way:

If  $\text{prob} = \text{NormDist}(\text{value}, m, \text{sd})$ , then  $\text{NormInv}(\text{prob}, m, \text{sd}) = \text{value}$

**Limitations:**

All arguments must be numeric, else NULL will be returned.

**Examples and results:**

Examples and results

| Example                          | Result         |
|----------------------------------|----------------|
| <code>NormDist(0.5, 0, 1)</code> | Returns 0.6915 |

### NormInv

**NormInv()** returns the inverse of the normal cumulative distribution for the specified mean and standard deviation.

**Syntax:**

```
NormInv(prob, mean, standard_dev)
```

**Return data type:** number

**Arguments:**

NORMINV arguments

| Argument     | Description                                                                                 |
|--------------|---------------------------------------------------------------------------------------------|
| prob         | A probability associated with the normal distribution. It must be a number between 0 and 1. |
| mean         | A value stating the arithmetic mean for the distribution.                                   |
| standard_dev | A positive value stating the standard deviation of the distribution.                        |

This function is related to the **NormDist** function in the following way:

If `prob = NormDist(value, m, sd)`, then `NormInv(prob, m, sd) = value`

### Limitations:

All arguments must be numeric, else NULL will be returned.

### Examples and results:

#### Examples and results

| Example                               | Result         |
|---------------------------------------|----------------|
| <code>NormInv(0.6914625, 0, 1)</code> | Returns 0.5000 |

## PoissonDist

`PoissonDist()` returns the accumulated probability of the Poisson distribution.

### Syntax:

```
PoissonDist(value, mean)
```

**Return data type:** number

#### Arguments

| Argument           | Description                                                                               |
|--------------------|-------------------------------------------------------------------------------------------|
| <code>value</code> | The value at which you want to evaluate the distribution. The value must not be negative. |
| <code>mean</code>  | A positive number defining the average outcome.                                           |

This function is related to the `PoissonInv` function in the following way:

If `prob = PoissonDist(value, mean)`, then `PoissonInv(prob, mean) = value`

## PoissonFrequency

`PoissonFrequency()` returns the Poisson probability distribution.

### Syntax:

```
PoissonFrequency(value, mean)
```

**Return data type:** number

#### Arguments

| Argument           | Description                                                                               |
|--------------------|-------------------------------------------------------------------------------------------|
| <code>value</code> | The value at which you want to evaluate the distribution. The value must not be negative. |
| <code>mean</code>  | A positive number defining the average outcome.                                           |

### PoissonInv

PoissonInv() returns the inverse of the accumulated probability of the Poisson distribution.

#### Syntax:

```
PoissonInv(prob, mean)
```

**Return data type:** number

#### Arguments

| Argument | Description                                                                                              |
|----------|----------------------------------------------------------------------------------------------------------|
| prob     | A probability associated with the Poisson-probability distribution. It must be a number between 0 and 1. |
| mean     | A positive number defining the average outcome.                                                          |

This function is related to the PoissonDist function in the following way:

If  $prob = \text{PoissonDist}(value, mean)$ , then  $\text{PoissonInv}(prob, mean) = value$

### TDensity

TDensity() returns the value for the student's  $t$  density function where a numeric value is a calculated value of  $t$  for which the probability is to be computed.

#### Syntax:

```
TDensity(value, degrees_freedom)
```

**Return data type:** number

#### Arguments

| Argument        | Description                                                                               |
|-----------------|-------------------------------------------------------------------------------------------|
| value           | The value at which you want to evaluate the distribution. The value must not be negative. |
| degrees_freedom | A positive integer stating the number of degrees of freedom.                              |

### TDist

TDist() returns the probability for the Student's  $t$ -distribution where a numeric value is a calculated value of  $t$  for which the probability is to be computed.

#### Syntax:

```
TDist(value, degrees_freedom, tails)
```

**Return data type:** number

**Arguments:**

TDIST arguments

| Argument        | Description                                                                        |
|-----------------|------------------------------------------------------------------------------------|
| value           | The value at which you want to evaluate the distribution and must not be negative. |
| degrees_freedom | A positive integer stating the number of degrees of freedom.                       |
| tails           | Must be either 1 (one-tailed distribution) or 2 (two-tailed distribution).         |

This function is related to the **TInv** function in the following way:

If  $\text{prob} = \text{TDist}(\text{value}, \text{df}, 2)$ , then  $\text{TInv}(\text{prob}, \text{df}) = \text{value}$

**Limitations:**

All arguments must be numeric, else NULL will be returned.

**Examples and results:**

Examples and results

| Example                      | Result         |
|------------------------------|----------------|
| <code>TDist(1, 30, 2)</code> | Returns 0.3253 |

### TInv

**TInv()** returns the t-value of the Student's t-distribution as a function of the probability and the degrees of freedom.

**Syntax:**

```
TInv(prob, degrees_freedom)
```

**Return data type:** number

**Arguments:**

TINV arguments

| Argument        | Description                                                                                       |
|-----------------|---------------------------------------------------------------------------------------------------|
| prob            | A two-tailed probability associated with the t-distribution. It must be a number between 0 and 1. |
| degrees_freedom | An integer stating the number of degrees of freedom.                                              |

### Limitations:

All arguments must be numeric, else NULL will be returned.

This function is related to the **TDist** function in the following way:

If  $\text{prob} = \text{TDist}(\text{value}, \text{df}, 2)$ , then  $\text{TInv}(\text{prob}, \text{df}) = \text{value}$ .

### Examples and results:

#### Examples and results

| Example                          | Result         |
|----------------------------------|----------------|
| <code>TInv(0.3253086, 30)</code> | Returns 1.0000 |

## String functions

This section describes functions for handling and manipulating strings. In the functions below, the parameters are expressions where **s** should be interpreted as a string.

All functions can be used in both the load script and in chart expressions, except for **Evaluate** which can only be used in the load script.

### String functions overview

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

#### ApplyCodepage

Applies a different codepage to the field or text stated in the expression. The codepage must be in number format.

```
ApplyCodepage(text, codepage)
```

#### Capitalize

**Capitalize()** returns the string with all words in initial uppercase letters.

```
Capitalize(text)
```

#### Chr

**Chr()** returns the Unicode character corresponding to the input integer.

```
Chr(int)
```

#### Evaluate

**Evaluate()** finds if the input text string can be evaluated as a valid QlikView expression, and if so, returns the value of the expression as a string. If the input string is not a valid expression, NULL is returned.

```
Evaluate(expression_text)
```

### FindOneOf

**FindOneOf()** searches a string to find the position of the occurrence of any character from a set of provided characters. The position of the first occurrence of any character from the search set is returned unless a third argument (with a value greater than 1) is supplied. If no match is found, **0** is returned.

```
FindOneOf (text, char_set[, count])
```

### Hash128

**Hash128()** returns a 128-bit hash of the combined input expression values. The result is a 22-character string.

```
Hash128 (expr{, expression})
```

### Hash160

**Hash160()** returns a 160-bit hash of the combined input expression values. The result is a 27-character string.

```
Hash160 (expr{, expression})
```

### Hash256

**Hash256()** returns a 256-bit hash of the combined input expression values. The result is a 43-character string.

```
Hash256 (expr{, expression})
```

### Index

**Index()** searches a string to find the starting position of the nth occurrence of a provided substring. An optional third argument provides the value of n, which is 1 if omitted. A negative value searches from the end of the string. The positions in the string are numbered from **1** and up.

```
Index (text, substring[, count])
```

### KeepChar

**KeepChar()** returns a string consisting of the first string, 'text', less any of the characters NOT contained in the second string, "keep\_chars".

```
KeepChar (text, keep_chars)
```

### Left

**Left()** returns a string consisting of the first (left-most) characters of the input string, where the number of characters in the returned string is determined by the second argument.

```
Left (text, count)
```

### Len

**Len()** returns the length of the input string.

```
Len (text)
```

### Lower

**Lower()** converts all the characters in the input string to lower case.

**Lower** (text)

### LTrim

**LTrim()** returns the input string trimmed of any leading spaces.

**LTrim** (text)

### Mid

**Mid()** returns the part of the input string starting at the position of the character defined by the second argument, 'start', and returning the number of characters defined by the third argument, 'count'. If 'count' is omitted, the rest of the input string is returned. The first character in the input string is numbered 1.

**Mid** (text, start[, count])

### Ord

**Ord()** returns the Unicode code point number of the first character of the input string.

**Ord** (char )

### PurgeChar

**PurgeChar()** returns a string consisting of the characters contained in the input string ('text'), excluding any that appear in the second argument ('remove\_chars').

**PurgeChar** (text, remove\_chars)

### Repeat

**Repeat()** forms a string consisting of the input string repeated the number of times defined by the second argument.

**Repeat** (text[, repeat\_count])

### Replace

**Replace()** returns a string after replacing all occurrences of a given substring within the input string with another substring. The function is non-recursive and works from left to right.

**Replace** (text, from\_str, to\_str)

### Right

**Right()** returns a string consisting of the of the last (right-most) characters of the input string, where the number of characters is determined by the second argument.

**Right** (text, count )

### RTrim

**RTrim()** returns the input string trimmed of any trailing spaces.

**RTrim** (text)

### SubField

**Subfield()** is used to extract substring components from a parent string field, where the original record fields consist of two or more parts separated by a delimiter.

```
SubField (text, delimiter[, field_no])
```

### SubStringCount

**SubStringCount()** returns the number of occurrences of the specified substring in the input string text. If there is no match, 0 is returned.

```
SubStringCount (text , substring)
```

### TextBetween

**TextBetween()** returns the text in the input string that occurs between the characters specified as delimiters.

```
TextBetween (text, sub_string)
```

### Trim

**Trim()** returns the input string trimmed of any leading and trailing spaces.

```
Trim (text)
```

### Upper

**Upper()** converts all the characters in the input string to upper case for all text characters in the expression. Numbers and symbols are ignored.

```
Upper (text)
```

### Capitalize

**Capitalize()** returns the string with all words in initial uppercase letters.

#### Syntax:

```
Capitalize(text)
```

**Return data type:** string

#### Examples and results:

Examples and results

| Example                         | Result                   |
|---------------------------------|--------------------------|
| capitalize ( 'my little pony' ) | Returns 'My Little Pony' |
| capitalize ( 'AA bb cC Dd' )    | Returns 'Aa Bb Cc Dd'    |

### Chr

**Chr()** returns the Unicode character corresponding to the input integer.

#### Syntax:

```
Chr (int)
```

**Return data type:** string

**Examples and results:**

| Examples and results |                        |
|----------------------|------------------------|
| Example              | Result                 |
| Chr(65)              | Returns the string 'A' |
| Chr(163)             | Returns the string '£' |
| Chr(35)              | Returns the string '#' |

### Evaluate

**Evaluate()** finds if the input text string can be evaluated as a valid QlikView expression, and if so, returns the value of the expression as a string. If the input string is not a valid expression, NULL is returned.

**Syntax:**

```
Evaluate(expression_text)
```

**Return data type:** dual

*This string function can not be used in chart expressions.*

**Examples and results:**

| Examples and results |              |
|----------------------|--------------|
| Example              | Result       |
| Evaluate ( 5 * 8 )   | Returns '40' |

### FindOneOf

**FindOneOf()** searches a string to find the position of the occurrence of any character from a set of provided characters. The position of the first occurrence of any character from the search set is returned unless a third argument (with a value greater than 1) is supplied. If no match is found, 0 is returned.

**Syntax:**

```
FindOneOf(text, char_set[, count])
```

**Return data type:** integer

**Arguments:**

FindOneOf arguments

| Argument | Description                                                                                                                   |
|----------|-------------------------------------------------------------------------------------------------------------------------------|
| text     | The original string.                                                                                                          |
| char_set | A set of characters to search for in text.                                                                                    |
| count    | Defines which occurrence of any of the character to search for. For example, a value of 2 searches for the second occurrence. |

**Examples and results:**

Examples and results

| Example                                         | Result                                                                                                                               |
|-------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| FindOneOf( 'my example text string', 'et%s')    | Returns '4'.                                                                                                                         |
| FindOneOf( 'my example text string', 'et%s', 3) | Returns '12'. Because the search is for any of the characters: e, t, % or s, and "t" is the third occurrence, and is in position 12. |
| FindOneOf( 'my example text string', 'æ%&!')    | Returns '0'.                                                                                                                         |

### Hash128

**Hash128()** returns a 128-bit hash of the combined input expression values. The result is a 22-character string.

**Syntax:**

```
Hash128 (expr{, expression})
```

**Return data type:** string

**Example:**

```
Hash128 ('abc', 'xyz', '123')
Hash128 (Region, Year, Month)
```

### Hash160

**Hash160()** returns a 160-bit hash of the combined input expression values. The result is a 27-character string.

**Syntax:**

```
Hash160 (expr{, expression})
```

**Return data type:** string

**Example:**

```
Hash160 ('abc', 'xyz', '123')
Hash160 (Region, Year, Month)
```

### Hash256

**Hash256()** returns a 256-bit hash of the combined input expression values. The result is a 43-character string.

**Syntax:**

```
Hash256(expr{, expression})
```

**Return data type:** string

**Example:**

```
Hash256 ('abc', 'xyz', '123')
Hash256 (Region, Year, Month)
```

### Index

**Index()** searches a string to find the starting position of the nth occurrence of a provided substring. An optional third argument provides the value of n, which is 1 if omitted. A negative value searches from the end of the string. The positions in the string are numbered from 1 and up.

**Syntax:**

```
Index(text, substring[, count])
```

**Return data type:** integer

**Arguments:**

Index arguments

| Argument  | Description                                                                                                                                                                                                                                                                                 |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| text      | The original string.                                                                                                                                                                                                                                                                        |
| substring | A string of characters to search for in text.<br><div style="border: 1px solid #ccc; padding: 5px; margin-top: 10px;"> <i>If the substring does not exist in the text, <b>Index</b> returns 0.</i></div> |
| count     | Defines which occurrence of <b>substring</b> to search for. For example, a value of 2 searches for the second occurrence.                                                                                                                                                                   |

### Examples and results:

Examples and results

| Example                                                          | Result                                                         |
|------------------------------------------------------------------|----------------------------------------------------------------|
| Index( 'abcdefg', 'cd' )                                         | Returns 3                                                      |
| Index( 'abcdabcd', 'b', 2)                                       | Returns 6 (the second occurrence of 'b')                       |
| Index( 'abcdabcd', 'b',-2)                                       | Returns 2 (the second occurrence of 'b' starting from the end) |
| Left( Date, Index( Date, '-' ) -1 ) where Date = 1997-07-14      | Returns 1997                                                   |
| Mid( Date, Index( Date, '-', 2 ) -2, 2 ) where Date = 1997-07-14 | Returns 07                                                     |
|                                                                  | Returns 0 ('x' does not exist in the string 'abc')             |
|                                                                  | Returns 0 (there is no 2nd occurrence of 'a')                  |

### KeepChar

**KeepChar()** returns a string consisting of the first string, 'text', less any of the characters NOT contained in the second string, "keep\_chars".

#### Syntax:

```
KeepChar (text, keep_chars)
```

**Return data type:** string

#### Arguments:

KeepChar arguments

| Argument   | Description                                            |
|------------|--------------------------------------------------------|
| text       | The original string.                                   |
| keep_chars | A string containing the characters in text to be kept. |

### Examples and results:

Examples and results

| Example                        | Result          |
|--------------------------------|-----------------|
| KeepChar ( 'a1b2c3', '123' )   | Returns '123'.  |
| KeepChar ( 'a1b2c3', '1234' )  | Returns '123'.  |
| KeepChar ( 'a1b22c3', '1234' ) | Returns '1223'. |
| KeepChar ( 'a1b2c3', '312' )   | Returns '123'   |

### Left

**Left()** returns a string consisting of the first (left-most) characters of the input string, where the number of characters in the returned string is determined by the second argument.

#### Syntax:

```
Left(text, count)
```

**Return data type:** string

#### Arguments:

##### Left arguments

| Argument | Description                                                                                      |
|----------|--------------------------------------------------------------------------------------------------|
| text     | The original string.                                                                             |
| count    | Defines the number of characters to included from the left-hand part of the string <b>text</b> . |

#### Examples and results:

##### Examples and results

| Example           | Result        |
|-------------------|---------------|
| Left('abcdef', 3) | Returns 'abc' |

the *Index (page 1550)*, which allows more complex string analysis.

### Len

**Len()** returns the length of the input string.

#### Syntax:

```
Len(text)
```

**Return data type:** integer

#### Examples and results:

##### Examples and results

| Example       | Result      |
|---------------|-------------|
| Len ('Peter') | Returns '5' |

### LevenshteinDist

**LevenshteinDist()** returns the Levenshtein distance between two strings. It is defined as the minimum number of single-character edits (insertions, deletions, or substitutions) required to change one string into the other. The function is useful for fuzzy string comparisons.

### Syntax:

```
LevenshteinDist(text1, text2)
```

**Return data type:** integer

### Examples and results:

| Example                              | Result      |
|--------------------------------------|-------------|
| LevenshteinDist('Kitten', 'Sitting') | Returns '3' |

### Lower

**Lower()** converts all the characters in the input string to lower case.

### Syntax:

```
Lower(text)
```

**Return data type:** string

### Examples and results:

#### Examples and results

| Example       | Result         |
|---------------|----------------|
| Lower('abcd') | Returns 'abcd' |

### LTrim

**LTrim()** returns the input string trimmed of any leading spaces.

### Syntax:

```
LTrim(text)
```

**Return data type:** string

### Examples and results:

#### Examples and results

| Example         | Result        |
|-----------------|---------------|
| LTrim( ' abc' ) | Returns 'abc' |
| LTrim( 'abc ' ) | Returns 'abc' |

### Mid

**Mid()** returns the part of the input string starting at the position of the character defined by the second argument, 'start', and returning the number of characters defined by the third argument, 'count'. If 'count' is omitted, the rest of the input string is returned. The first character in the input string is numbered 1.

#### Syntax:

```
Mid(text, start[, count])
```

**Return data type:** string

#### Arguments:

Mid arguments

| Argument | Description                                                                                                                        |
|----------|------------------------------------------------------------------------------------------------------------------------------------|
| text     | The original string.                                                                                                               |
| start    | Integer defining the position of the first character in text to include.                                                           |
| count    | Defines the string length of the output string. If omitted, all characters from the position defined by <b>start</b> are included. |

#### Examples and results:

Examples and results

| Example              | Result         |
|----------------------|----------------|
| Mid('abcdef', 3 )    | Returns 'cdef' |
| Mid('abcdef', 3, 2 ) | Returns 'cd'   |

### Ord

**Ord()** returns the Unicode code point number of the first character of the input string.

#### Syntax:

```
Ord(char)
```

**Return data type:** integer

Examples and results

| Example   | Result                  |
|-----------|-------------------------|
| ord('A')  | Returns the integer 65. |
| ord('Ab') | Returns the integer 65. |

### PurgeChar

**PurgeChar()** returns a string consisting of the characters contained in the input string ('text'), excluding any that appear in the second argument ('remove\_chars').

**Syntax:**

```
PurgeChar (text, remove_chars)
```

**Return data type:** string

**Arguments:**

PurgeChar arguments

| Argument     | Description                                               |
|--------------|-----------------------------------------------------------|
| text         | The original string.                                      |
| remove_chars | A string containing the characters in text to be removed. |

**Return data type:** string

**Examples and results:**

Examples and results

| Example                       | Result        |
|-------------------------------|---------------|
| PurgeChar ( 'a1b2c3', '123' ) | Returns 'abc' |
| PurgeChar ( 'a1b2c3', '312' ) | Returns 'abc' |

### Repeat

**Repeat()** forms a string consisting of the input string repeated the number of times defined by the second argument.

**Syntax:**

```
Repeat (text[, repeat_count])
```

**Return data type:** string

**Arguments:**

Repeat arguments

| Argument     | Description                                                                                                   |
|--------------|---------------------------------------------------------------------------------------------------------------|
| text         | The original string.                                                                                          |
| repeat_count | Defines the number of times the characters in the string <b>text</b> are to be repeated in the output string. |

### Examples and results:

#### Examples and results

| Example                                                     | Result          |
|-------------------------------------------------------------|-----------------|
| <code>Repeat( ' * ', rating )</code> when <b>rating</b> = 4 | Returns '*****' |

### Replace

**Replace()** returns a string after replacing all occurrences of a given substring within the input string with another substring. The function is non-recursive and works from left to right.

#### Syntax:

```
Replace(text, from_str, to_str)
```

**Return data type:** string

#### Arguments:

#### Replace arguments

| Argument | Description                                                                                     |
|----------|-------------------------------------------------------------------------------------------------|
| text     | The original string.                                                                            |
| from_str | A string which may occur one or more times within the input string <b>text</b> .                |
| to_str   | The string that will replace all occurrences of <b>from_str</b> within the string <b>text</b> . |

### Examples and results:

#### Examples and results

| Example                                     | Result            |
|---------------------------------------------|-------------------|
| <code>replace('abccde', 'cc', 'xyz')</code> | Returns 'abxyzde' |

### Right

**Right()** returns a string consisting of the of the last (right-most) characters of the input string, where the number of characters is determined by the second argument.

#### Syntax:

```
Right(text, count)
```

**Return data type:** string

**Arguments:**

Right arguments

| Argument | Description                                                                                          |
|----------|------------------------------------------------------------------------------------------------------|
| text     | The original string.                                                                                 |
| count    | Defines the number of characters to be included from the right-hand part of the string <b>text</b> . |

**Examples and results:**

Examples and results

| Example                         | Result        |
|---------------------------------|---------------|
| <code>Right('abcdef', 3)</code> | Returns 'def' |

### RTrim

**RTrim()** returns the input string trimmed of any trailing spaces.

**Syntax:**

```
RTrim(text)
```

**Return data type:** string

**Examples and results:**

Examples and results

| Example                    | Result        |
|----------------------------|---------------|
| <code>RTrim(' abc')</code> | Returns 'abc' |
| <code>RTrim('abc ')</code> | Returns 'abc' |

### SubField

**Subfield()** is used to extract substring components from a parent string field, where the original record fields consist of two or more parts separated by a delimiter.

The **Subfield()** function can be used, for example, to extract first name and surname from a list of records consisting of full names, the component parts of a path name, or for extracting data from comma-separated tables.

If you use the **Subfield()** function in a **LOAD** statement with the optional `field_no` parameter left out, one full record will be generated for each substring. If several fields are loaded using **Subfield()** the Cartesian products of all combinations are created.

### Syntax:

```
SubField(text, delimiter[, field_no])
```

**Return data type:** string

### Arguments:

SubField arguments

| Argument  | Description                                                                                                                                                                                                                                                                                                                                                                   |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| text      | The original string. This can be a hard-coded text, a variable, a dollar-sign expansion, or another expression.                                                                                                                                                                                                                                                               |
| delimiter | A character within the input <b>text</b> that divides the string into component parts.                                                                                                                                                                                                                                                                                        |
| field_no  | The optional third argument is an integer that specifies which of the substrings of the parent string <b>text</b> is to be returned. <ul style="list-style-type: none"> <li>• If <b>field_no</b> is a positive value, substrings are extracted from left to right.</li> <li>• If <b>field_no</b> is a negative value, substrings are extracted from right to left.</li> </ul> |

*SubField() can be used instead of using complex combinations of functions such as Len(), Right(), Left(), Mid(), and other string functions.*

### Examples and results:

Examples 1-3

| Example                         | Result                  |
|---------------------------------|-------------------------|
| SubField('abc;cde;efg', ';', 2) | Returns 'cde'           |
| SubField('', ';', 1)            | Returns NULL            |
| SubField(';', ';', 1)           | Returns an empty string |

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
FullName:
LOAD * inline [
Name
'Dave Owen'
'Joe Tem'
];

SepNames:
Load Name,
SubField(Name, ' ',1) as FirstName,
SubField(Name, ' ',-1) as Surname
Resident FullName;
Drop Table FullName;
```

## 9 Script syntax and chart functions

---

Example 4

| Name      | FirstName | Surname |
|-----------|-----------|---------|
| Dave Owen | Dave      | Owen    |
| Joe Tem   | Joe       | Tem     |

Suppose you have a variable that holds a path name vMyPath,

```
set vMyPath=\Users\ext_jrb\Documents\Qlik\Sense\Apps;
```

In a text & image chart, you can add a measure such as:

subField(vMyPath, '\', -3), which results in 'Qlik', because it is the substring third from the right-hand end of the variable vMyPath.

This example shows how multiple rows are created from a single instance of **Subfield()**.

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
LOAD DISTINCT
Player,
SubField(Project,',') as Project;
```

```
Load * inline [
Player|Project
Neil|Music,OST
Jo|Music
Mike|Music,OST,Video
] (delimiter is '|');
```

Example 5

| Player | Project |
|--------|---------|
| Neil   | Music   |
| Neil   | OST     |
| Jo     | Music   |
| Mike   | Music   |
| Mike   | OST     |
| Mike   | Video   |

This example shows how using multiple instances of the **Subfield()** function, each with the field\_no parameter left out, from within the same **LOAD** statement creates Cartesian products of all combinations. The **DISTINCT** option is used to avoid creating duplicate record.

Add the example script to your document and run it. Then add, at least, the fields listed in the results column to a sheet in your document to see the result.

```
LOAD DISTINCT
Instrument,
SubField(Player,',') as Player,
SubField(Project,',') as Project;
```

```
Load * inline [
Instrument|Player|Project
Guitar|Neil, Mike|Music, Video
Guitar|Neil|Music, OST
Synth|Neil, Jen|Music, Video, OST
Synth|Jo|Music
Guitar|Neil, Mike|Music, OST
] (delimiter is '|');
```

Example 6

| Instrument | Player | Project |
|------------|--------|---------|
| Guitar     | Mike   | Music   |
| Guitar     | Mike   | Video   |
| Guitar     | Mike   | OST     |
| Guitar     | Neil   | Music   |
| Guitar     | Neil   | Video   |
| Guitar     | Neil   | OST     |
| Synth      | Jen    | Music   |
| Synth      | Jen    | Video   |
| Synth      | Jen    | OST     |
| Synth      | Jo     | Music   |
| Synth      | Neil   | Music   |
| Synth      | Neil   | Video   |
| Synth      | Neil   | OST     |

### SubStringCount

**SubStringCount()** returns the number of occurrences of the specified substring in the input string **text**. If there is no match, 0 is returned.

#### Syntax:

```
SubStringCount(text, sub_string)
```

**Return data type:** integer

#### Arguments:

SubStringCount arguments

| Argument   | Description                                                                      |
|------------|----------------------------------------------------------------------------------|
| text       | The original string.                                                             |
| sub_string | A string which may occur one or more times within the input string <b>text</b> . |

### Examples and results:

Examples and results

| Example                                 | Result      |
|-----------------------------------------|-------------|
| substringCount ( 'abcdefgdcxyz', 'cd' ) | Returns '2' |
| substringCount ( 'abcdefgdcxyz', 'dc' ) | Returns '0' |

### TextBetween

**TextBetween()** returns the text in the input string that occurs between the characters specified as delimiters.

#### Syntax:

```
TextBetween(text, delimiter1, delimiter2[, n])
```

**Return data type:** string

#### Arguments:

TextBetween arguments

| Argument   | Description                                                                                                                                                                                             |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| text       | The original string.                                                                                                                                                                                    |
| delimiter1 | Specifies the first delimiting character (or string) to search for in <b>text</b> .                                                                                                                     |
| delimiter2 | Specifies the second delimiting character (or string) to search for in <b>text</b> .                                                                                                                    |
| n          | Defines which occurrence of the delimiter pair to search between. For example, a value of 2 returns the characters between the second occurrence of delimiter1 and the second occurrence of delimiter2. |

### Examples and results:

Examples and results

| Example                               | Result        |
|---------------------------------------|---------------|
| TextBetween('<abc>', '<', '>')        | Returns 'abc' |
| TextBetween('<abc><de>', '<', '>', 2) | Returns 'de'  |

### Trim

**Trim()** returns the input string trimmed of any leading and trailing spaces.

#### Syntax:

```
Trim(text)
```

**Return data type:** string

**Examples and results:**

Examples and results

| Example                      | Result        |
|------------------------------|---------------|
| <code>Trim( ' abc' )</code>  | Returns 'abc' |
| <code>Trim( 'abc ' )</code>  | Returns 'abc' |
| <code>Trim( ' abc ' )</code> | Returns 'abc' |

### Upper

**Upper()** converts all the characters in the input string to upper case for all text characters in the expression. Numbers and symbols are ignored.

**Syntax:**

```
Upper (text)
```

**Return data type:** string

**Examples and results:**

Examples and results

| Example                     | Result         |
|-----------------------------|----------------|
| <code>Upper(' abcd')</code> | Returns 'ABCD' |

## System functions

System functions provide functions for accessing system, device and QlikView document properties.

### System functions overview

Some of the functions are described further after the overview. For those functions, you can click the function name in the syntax to immediately access the details for that specific function.

#### Author

This function returns a string containing the author property of the current document. It can be used in both the load script and in a chart expression.

```
Author ()
```

#### ClientPlatform

This function returns the user agent string of the client browser. It can be used in both the load script and in a chart expression.

### Example:

```
Mozilla/5.0 (Windows NT 6.1; WOW64) AppleWebKit/537.36 (KHTML, like Gecko)
Chrome/35.0.1916.114 Safari/537.36
```

```
ClientPlatform()
```

### ComputerName

This function returns a string containing the name of the computer as returned by the operating system. It can be used in both the load script and in a chart expression.

```
ComputerName()
```

### DocumentName

This function returns a string containing the name of the current QlikView document, without path but with extension. It can be used in both the load script and in a chart expression.

```
DocumentName()
```

### DocumentPath

This function returns a string containing the full path to the current QlikView document. It can be used in both the load script and in a chart expression.

```
DocumentPath()
```

### DocumentTitle

This function returns a string containing the title of the current QlikView document. It can be used in both the load script and in a chart expression.

```
DocumentTitle()
```

### GetCollationLocale

This script function returns the culture name of the collation locale that is used. If the variable CollationLocale has not been set, the actual user machine locale is returned.

```
GetCollationLocale()
```

### GetActiveSheetID

Returns a string containing the ID of the active sheet

```
GetActiveSheetID()
```

### GetExtendedProperty

This function returns the value of a named extended property in the sheet object with the given object ID. If **objectid** is not given, the sheet object containing the expression will be used. An extended property is defined for the extension object in its definition file.

```
GetExtendedProperty - chart function(name[, objectid])
```

### GetObjectField

**GetObjectField()** returns the name of the dimension. **Index** is an optional integer denoting the dimension that should be returned.

```
GetObjectField - chart function ([index])
```

### GetRegistryString

This function returns the value of a key in the Windows registry. It can be used in both the load script and in a chart expression.

```
GetRegistryString(path, key)
```

### Input

This function can be used in the script only and opens an input box that prompts the user for a value during the script execution. The parameters **cue** and **caption** are used as message and caption texts, respectively. The function returns the entered value.

The input box function returns NULL if the dialog is canceled, closed or cannot be shown.

### Example:

```
Load
Input('Enter value', 'Input box') as v,
Recno () as r
autogenerate 3;
Input(str cue [, str caption])
```

### IsPartialReload

Returns -1 (True) if the current reload is partial, otherwise 0 (False). This only works in the script.

```
IsPartialReload()
```

### MsgBox

This function can be used in the script only and opens a message box during the script execution. The parameters **msg** and **caption** are used as message and caption texts, respectively. The parameter **mb\_buttons** defines what buttons will be shown in the message box, according to:

- 0 or 'OK' for a single OK button,
- 1 or 'OKCANCEL' for two buttons, OK and Cancel,
- 2 or 'ABORTRETRYIGNORE' for three buttons, Abort, Retry and Ignore,
- 3 or 'YESNOCANCEL' for three buttons, Yes, No and Cancel,
- 4 or 'YESNO' for two buttons, Yes and No,
- 5 or 'RETRYCANCEL' for two buttons, Retry and Cancel.

The parameter **mb\_icons** defines what icon will be shown in the message box, according to:

- 0 or empty string for no icon,
- 16 or 'ICONHAND' for an icon with an X, used for critical errors,
- 32 or 'ICONQUESTION' for an icon with a question mark,
- 48 or 'ICONEXCLAMATION' for icon with an exclamation mark, used for minor errors, cautions and warnings
- 64 or 'ICONASTERISK' icon with an *i*, used for informational messages.

---

## 9 Script syntax and chart functions

---

The parameter **mb\_defbutton** defines what button will have focus when the message box is shown, according to:

- 0 or 'DEFBUTTON1' if the first button should have focus,
- 256 or 'DEFBUTTON2' if the second button should have focus,
- 512 or 'DEFBUTTON3' if the third button should have focus,
- 768 or 'DEFBUTTON4' if the fourth button should have focus.

The function returns an integer that shows what button has been pressed by the user, according to:

- 1 for OK,
- 2 for Cancel,
- 3 for Abort,
- 4 for Retry,
- 5 for Ignore,
- 6 for Yes,
- 7 for No

The parameter 3, 4 and 5 will internally be added, so if numeric values other than the above mentioned ones are used, you may get an unexpected combination of icons and buttons.

The message box function returns NULL if the dialog cannot be shown.

### Example:

```
Load
MsgBox('Message 2', 'msgbox', 'OKCANCEL', 'ICONASTERISK') as x, 2 as r
autogenerate 1;
MsgBox(str msg [, str caption [, mb_buttons [, mb_icons[, mb_defbutton]]])
```

### OSUser

This function returns a string containing the name of the current user as returned by the operating system. It can be used in both the load script and in a chart expression.

```
OSUser ()
```

### QlikViewVersion

This function returns the full QlikView version and build number as a string.

```
QlikViewVersion (page 1566) ()
```

### QVuser

Returns a string containing the name of the current QlikView user as entered in for section access.

```
QVuser ()
```

### ReloadTime

This function returns a timestamp for when the last data load finished. It can be used in both the load script and in a chart expression.

```
ReloadTime ()
```

### StateName

This chart function returns the state name of the object in which it is used. The QlikView developer can use this function to have dynamic text and colors when an object's state is changed. It is important to note that this function works on objects only. It cannot be used in a chart expression to determine the state that the expression refers to.

```
StateName - chart function()
```

### GetExtendedProperty - chart function

This function returns the value of a named extended property in the sheet object with the given object ID. If **objectid** is not given, the sheet object containing the expression will be used. An extended property is defined for the extension object in its definition file.

#### Syntax:

```
GetExtendedProperty (name[, objectid])
```

#### Example:

```
GetExtendedProperty ('Greeting')
```

### GetObjectField - chart function

**GetObjectField()** returns the name of the dimension. **Index** is an optional integer denoting the dimension that should be returned.

#### Syntax:

```
GetObjectField ([index])
```

#### Example:

```
GetObjectField(2)
```

### ProductVersion

This function returns the full product version and build number as a string. Using **ProductVersion** makes the version number compatible with the other Qlik products such as Qlik Sense.

#### Syntax:

```
ProductVersion()
```

### QlikViewVersion

This function returns the full QlikView version and build number as a string.

#### Syntax:

```
QlikViewVersion()
```

*Using **ProductVersion** will make the version number compatible with the other Qlik products such as Qlik Sense.*

See also: [ProductVersion](#)

### StateName - chart function

This chart function returns the state name of the object in which it is used. The QlikView developer can use this function to have dynamic text and colors when an object's state is changed. It is important to note that this function works on objects only. It cannot be used in a chart expression to determine the state that the expression refers to.

#### Syntax:

```
StateName ()
```

Alternate states can be defined under **Settings > Document Properties > General > Alternate States**.

#### Example 1:

```
Dynamic Text
='Region - ' & if(StateName() = '$', 'Default', StateName())
```

#### Example 2:

```
Dynamic Colors
if(StateName() = 'Group 1', rgb(152, 171, 206),
 if(StateName() = 'Group 2', rgb(187, 200, 179),
 rgb(210, 210, 210)
)
)
```

## Table functions

The table functions return information about the data table which is currently being read. If no table name is specified and the function is used within a **LOAD** statement, the current table is assumed.

All functions can be used in the load script, while only **NoOfRows** can be used in a chart expression.

### Table functions overview

Some of the functions are described further after the overview. For those functions, you can click the function name in the syntax to immediately access the details for that specific function.

### FieldName

The **FieldName** script function returns the name of the field with the specified number within a previously loaded table. If the function is used within a **LOAD** statement, it must not reference the table currently being loaded.

```
FieldName (field_number ,table_name)
```

### FieldNumber

The **FieldNumber** script function returns the number of a specified field within a previously loaded table. If the function is used within a **LOAD** statement, it must not reference the table currently being loaded.

```
FieldNumber (field_name ,table_name)
```

### NoOfFields

The **NoOfFields** script function returns the number of fields in a previously loaded table. If the function is used within a **LOAD** statement, it must not reference the table currently being loaded.

```
NoOfFields (table_name)
```

### NoOfRows

The **NoOfRows** function returns the number of rows (records) in a previously loaded table. If the function is used within a **LOAD** statement, it must not reference the table currently being loaded.

```
NoOfRows (table_name)
```

### NoOfTables

This script function returns the number of tables previously loaded.

```
NoOfTables ()
```

### TableName

This script function returns the name of the table with the specified number.

```
TableName (table_number)
```

### TableNumber

This script function returns the number of the specified table. The first table has number 0.

If table\_name does not exist, no value is returned. If a function is set to return a functional value, this variable is not initialized. As a workaround, you can specify `LET vImaginaryTabNum = If(TableNumber('NotExistingTable')>=0,TableNumber('NotExistingTable'),'NULL')` ;

```
TableNumber (table_name)
```

### Example:

In this example, we want to create a table with information about the tables and fields that have been loaded.

First we load some sample data. This creates the two tables that will be used to illustrate the table functions described in this section.

Characters:

```
Load Chr(RecNo()+Ord('A')-1) as Alpha, RecNo() as Num autogenerate 26;
```

ASCII:

```
Load
 if(RecNo()>=65 and RecNo()<=90,RecNo()-64) as Num,
 Chr(RecNo()) as AsciiAlpha,
 RecNo() as AsciiNum
autogenerate 255
where (RecNo()>=32 and RecNo()<=126) or RecNo()>=160 ;
```

Next, we iterate through the tables that have been loaded, using the **NoOfTables** function, and then through the fields of each table, using the **NoOfFields** function, and load information using the table functions.

```
//Iterate through the loaded tables
For t = 0 to NoOfTables() - 1

//Iterate through the fields of table
For f = 1 to NoOfFields(TableName$(t))
 Tables:
 Load
 TableName$(t) as Table,
 TableNumber(TableName$(t)) as TableNo,
 NoOfRows(TableName$(t)) as TableRows,
 FieldName$(f),TableName$(t) as Field,
 FieldNumber(FieldName$(f),TableName$(t)),TableName$(t) as FieldNo
 Autogenerate 1;
Next f
Next t;
```

The resulting table Tables will look like this:

Tables table

| Table      | TableNo | TableRows | Field      | FieldNo |
|------------|---------|-----------|------------|---------|
| Characters | 0       | 26        | Alpha      | 1       |
| Characters | 0       | 26        | Num        | 2       |
| ASCII      | 1       | 191       | Num        | 1       |
| ASCII      | 1       | 191       | AsciiAlpha | 2       |
| ASCII      | 1       | 191       | AsciiNum   | 3       |

### FieldName

The **FieldName** script function returns the name of the field with the specified number within a previously loaded table. If the function is used within a **LOAD** statement, it must not reference the table currently being loaded.

**Syntax:**

```
FieldName(field_number ,table_name)
```

### Arguments:

#### FieldName arguments

| Argument     | Description                                           |
|--------------|-------------------------------------------------------|
| field_number | The field number of the field you want to reference.  |
| table_name   | The table containing the field you want to reference. |

### Example:

```
LET a = FieldName(4,'tab1');
```

## FieldNumber

The **FieldNumber** script function returns the number of a specified field within a previously loaded table. If the function is used within a **LOAD** statement, it must not reference the table currently being loaded.

### Syntax:

```
FieldNumber(field_name ,table_name)
```

#### FieldNumber arguments

| Argument   | Description                                 |
|------------|---------------------------------------------|
| field_name | The name of the field.                      |
| table_name | The name of the table containing the field. |

If the field field\_name does not exist in table\_name, or table\_name does not exist, the function returns 0.

### Example:

```
LET a = FieldNumber('Customer','tab1');
```

## NoOfFields

The **NoOfFields** script function returns the number of fields in a previously loaded table. If the function is used within a **LOAD** statement, it must not reference the table currently being loaded.

### Syntax:

```
NoOfFields(table_name)
```

### Arguments:

#### NoOfFields arguments

| Argument   | Description            |
|------------|------------------------|
| table_name | The name of the table. |

### Example:

```
LET a = NoOfFields('tab1');
```

### NoOfRows

The **NoOfRows** function returns the number of rows (records) in a previously loaded table. If the function is used within a **LOAD** statement, it must not reference the table currently being loaded.

#### Syntax:

```
NoOfRows (table_name)
```

#### Arguments:

| NoOfRows arguments |                        |
|--------------------|------------------------|
| Argument           | Description            |
| table_name         | The name of the table. |

#### Example:

```
LET a = NoOfRows('tab1');
```

## Trigonometric and hyperbolic functions

This section describes functions for performing trigonometric and hyperbolic operations. In all of the functions, the arguments are expressions resolving to angles measured in radians, where **x** should be interpreted as a real number.

All angles are measured in radians.

All functions can be used in both the load script and in chart expressions.

#### cos

Cosine of **x**. The result is a number between -1 and 1.

```
cos (x)
```

#### acos

Inverse cosine of **x**. The function is only defined if  $-1 \leq x \leq 1$ . The result is a number between 0 and  $\pi$ .

```
acos (x)
```

#### sin

Sine of **x**. The result is a number between -1 and 1.

```
sin (x)
```

#### asin

Inverse sine of **x**. The function is only defined if  $-1 \leq x \leq 1$ . The result is a number between  $-\pi/2$  and  $\pi/2$ .

```
asin (x)
```

#### tan

Tangent of **x**. The result is a real number.

```
tan(x)
```

### atan

Inverse tangent of **x**. The result is a number between  $-\pi/2$  and  $\pi/2$ .

```
atan(x)
```

### atan2

Two-dimensional generalization of the inverse tangent function. Returns the angle between the origin and the point represented by the coordinates **x** and **y**. The result is a number between  $-\pi$  and  $+\pi$ .

```
atan2(y, x)
```

### cosh

Hyperbolic cosine of **x**. The result is a positive real number.

```
cosh(x)
```

### sinh

Hyperbolic sine of **x**. The result is a real number.

```
sinh(x)
```

### tanh

Hyperbolic tangent of **x**. The result is a real number.

```
tanh(x)
```

### Examples:

The following script code loads a sample table, and then loads a table containing the calculated trigonometric and hyperbolic operations on the values.

```
SampleData:
```

```
LOAD * Inline
[Value
-1
0
1];
```

```
Results:
```

```
Load *,
cos(Value),
acos(Value),
sin(Value),
asin(Value),
tan(Value),
atan(Value),
atan2(Value, Value),
cosh(Value),
sinh(Value),
tanh(Value)
RESIDENT SampleData;
```

```
Drop Table SampleData;
```

### Window functions

Window functions perform calculations using values from multiple rows to produce a value for each row separately. Window functions can only be calculated once the entire table is read.

You can use window functions to perform operations such as:

- Comparing an individual number value in a row with the average, maximum, or minimum within the column.
- Calculating the rank of an individual value, either within the column or within the entire table.

Window functions do not change the number of records in the table but can perform similar tasks as aggregation functions or relational functions and range functions.

Each function is described further after the overview. You can also click the function name in the syntax to immediately access the details for that specific function.

#### Window

The **Window** function performs calculations from multiple rows, producing a value for each row separately.

```
Window - script function(input_expr, [partition1, partition2, ...], [sort_type, [sort_expr]], [filter_expr], [start_expr, end_expr]) [row_window_size]
```

#### WRank

The **WRank** function performs ranking calculations inside **Window**.

```
WRank - script function([TOTAL] expr[, mode[, fmt]])
```

### Window - script function

**Window()** performs calculations from multiple rows, producing a value for each row separately.

You can use the **Window** functions to perform operations such as:

- Comparing an individual number value in a row with the average, maximum, or minimum within the column.
- Calculating the rank of an individual value, either within the column or within the entire table.

The **Window** function does not change the number of records in the table but it can still perform similar tasks as aggregation, relational, and range functions.

The **Window** function must have a cache within the LOAD statement of the table you are working with to add to the table. For example:

```
[Transactions]:
Load
 *,
 window(avg(Expression1), [Num]);
```

LOAD

```
TransLineID,
TransID,
"Num",
Dim1,
Dim2,
Dim3,
Expression1,
Expression2,
Expression3
```

```
FROM [lib://DataFiles/transactions.qvd] (qvd);FROM [lib://AttachedFiles/transactions.qvd]
(qvd);
```

Window supports general functions, such as rounding or basic numerical operations. For example:

```
Load *, Round(window(Sum(Salary),Department)) as SumSalary
Load *, window(Sum(Salary),Department) + 5 as SumSalary
```

You can define a sliding window for the **Window** function. This sets the number of rows used when applying the **Window** function on the current row. For example, you could set the window to be the 3 previous rows and the 3 subsequent rows.

### Syntax:

```
Window (input_expr, [partition1, partition2, ...], [sort_type, [sort_expr]],
[filter_expr], [start_expr,end_expr])
```

Return data type: A new field added to the resulting table created by the LOAD statement.

### Arguments:

#### Arguments

| Argument                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| input_expr                | <p>The input expression calculated and returned by the function. It must be any expression based on an aggregation, such as <code>median(Salary)</code>. For example:</p> <pre>window(Median(Salary)) as MediansSalary</pre> <p>The input can also be a field name with no aggregation applied. In this case, <b>Window</b> treats it like the <b>Only()</b> function is applied to that field. For example:</p> <pre>window(Salary,Department) as wSalary</pre> <p>Optionally, you can define partitioning with the input expression. Partitioning is the same as the grouping achieved by the <b>group by</b> clause, with the difference that the result is added as a new column to the input table. Partitioning does not reduce the number of records of the input table. Multiple partition fields can be defined.</p> <p>Example:</p> <pre>LOAD window(Max(Sales), City, 'ASC', OrderDate, Sales &gt; 300) + AddMonths(OrderDate,-6) as MAX_Sales_City_Last_6_Mos, window(Avg(Sales), City, 'ASC', OrderDate, City = 'Portland') + AddMonths(OrderDate,-6) as Avg_Sales_Portland_Last_6_Mos, window(Max(Sales), City, 'ASC', OrderDate, Sales &gt; 300) + AddMonths(OrderDate,-12) as MAX_Sales_City_Last_12_Mos; LOAD     City,     Sales,     OrderDate FROM [lib://:DataFiles/Sales Data.xlsx]FROM [lib://AttachedFiles/Sales Data.xlsx] (ooxml, embedded labels, table is [Sales Data]);</pre> |
| partition1,<br>partition2 | <p>After <code>input_expr</code>, you can define any number of partitions. Partitions are fields that define which combinations to apply the aggregations with. The aggregation is applied separately with each partition. For example:</p> <pre>window(Avg(Salary), Unit, Department, Country) as AvgSalary</pre> <p>In the above, the partitions are <i>Unit</i>, <i>Department</i>, and <i>Country</i>.</p> <p>Partitions are not mandatory, but are required for proper windowing of fields.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Argument                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sort_type,<br>[sort_expr] | <p>Optionally, specify the sort type and the sort expression. sort_type can have one of two values:</p> <ul style="list-style-type: none"> <li>• ASC: Ascending sorting.</li> <li>• DESC: Descending sort.</li> </ul> <p>If you define sort_type, you need to define a sorting expression. This is an expression that decides the order of the rows within a partition.</p> <p>For example:</p> <pre>window(RecNo(), Department, 'ASC', Year)</pre> <p>In the above example, the results within the partition of sorted ascendingly by the <i>Year</i> field.</p> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> <p> <i>The sort type and sort expression are primarily only required with the <b>RecNo</b> and <b>WRank</b> functions.</i></p> </div> |
| filter_expr               | <p>Optionally, add a filter expression. This is a Boolean expression that decides whether the record should be included in the calculation or not.</p> <p>This parameter can be omitted completely, and the result should be that there is no filter.</p> <p>For example:</p> <pre>window(avg(Salary), Department, 'ASC', Age, EmployeeID=3 Or EmployeeID=7) as wAvgSalary) as wAvgSalaryIfEmpIs3or7</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Argument                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [start_ expr,end_ expr] | <p>Optionally, set the argument for sliding window functionality. A sliding window requires two arguments:</p> <ul style="list-style-type: none"> <li>• Start expression: The number of rows prior to the current row to include in the window.</li> <li>• End expression: The number of rows after the current row to include in the window.</li> </ul> <p>For example, if you wanted to include the 3 preceding rows, the current row, and the next following row:</p> <pre>window(concat(Text(Salary),'-'), Department, 'ASC', Age, Year&gt;0, -3, 1) as wSalaryDepartment</pre> <p>To indicate all preceding rows or all subsequent rows, you can use the <b>Unbounded()</b> function. For example, to include all preceding rows, the current row, and the following row:</p> <pre>window(concat(Text(Salary),'-'), Department, 'ASC', Age, Year&gt;0, UNBOUNDED(), 1) as wSlidingSalaryDepartment</pre> <p>For example, to include the third row from the current row and all subsequent rows:</p> <pre>window(concat(Text(Salary),'-'), Department, 'ASC', Age, Year&gt;0, 3, UNBOUNDED()) as wSlidingSalaryDepartment</pre> |

### Example - Adding a field containing an aggregation

Example: Adding a field containing an aggregation

#### Load script

Create a new tab in the data load editor, and then load the following data as an inline load. Create the table below in Qlik Sense to see the results.

Transactions:

```
Load
*,
window(Avg(transaction_amount),customer_id) as AvgCustTransaction;
```

```
Load * Inline [
transaction_id, transaction_date, transaction_amount, transaction_quantity, customer_id, size,
color_code
3750, 20180830, 23.56, 2, 2038593, L, Red
3751, 20180907, 556.31, 6, 203521, M, Orange
3752, 20180916, 5.75, 1, 5646471, S, Blue
3753, 20180922, 125.00, 7, 3036491, L, Black

### Limitations

**Window** has the following limitations:

- **Window** is a resource intensive function, particularly in terms of memory consumption.
- Chart expressions do not support **Window**.
- You cannot nest **Window** functions inside other **Window** functions.
- **Window** cannot be used inside an aggregation function.
- **Window** needs to be able to scan the whole table.
- **WRank()**, **RecNo()**, and **RowNo()** cannot be used with **Window** when using the sliding window functionality.

### WRank - script function

**WRank()** evaluates the rows of a table in the load script, and for each row, displays the relative position of the value of the field evaluated in the load script. When evaluating the table, the function compares the result with the result of the other rows containing the current partition and returns the ranking of the current row within the segment.

### Partitions in a table

|                   | Region   | Country                  | Population  | Rank(Population) |
|-------------------|----------|--------------------------|-------------|------------------|
| Column segment #1 | Americas | Mexico                   | 128,932,753 | 2                |
|                   | Americas | Canada                   | 37,742,154  | 3                |
|                   | Americas | United States of America | 331,002,651 | 1                |
| Column segment #2 | Europe   | Sweden                   | 10,099,265  | 4                |
|                   | Europe   | United Kingdom           | 67,886,011  | 2                |
|                   | Europe   | France                   | 65,273,511  | 3                |
|                   | Europe   | Germany                  | 83,783,942  | 1                |

**WRank** can only be used in a **Window** function. The **Window** function must include a sorting type and sorting expression. The ranking is applied on the sorting expression.

### Syntax:

```
WRank ([mode [, fmt]])
```

**Return data type:** dual

### Arguments:

#### Arguments

| Argument | Description                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mode     | Optionally, specifies the number representation of the function result.                                                                                                                                                                                                                                                                                                                                          |
| fmt      | Optionally, specifies the text representation of the function result.                                                                                                                                                                                                                                                                                                                                            |
| TOTAL    | If the table is one-dimensional, or if the script is preceded by the <b>TOTAL</b> qualifier, the function is evaluated along the entire column. If the table or table equivalent has multiple vertical dimensions, the current partition will include only rows with the same values as the current row in all dimension columns except for the column showing the last dimension in the inter-field sort order. |

The ranking is returned as a dual value, which in the case when each row has a unique ranking, is an integer between 1 and the number of rows in the current partition.

In the case where several rows share the same ranking, the text and number representation can be controlled with the **mode** and **fmt** parameters.

### mode

The first argument, **mode**, can take the following values:

#### mode values

| Value       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (default) | <p>If all ranks within the sharing group fall on the low side of the middle value of the entire ranking, all rows get the lowest rank within the sharing group.</p> <p>If all ranks within the sharing group fall on the high side of the middle value of the entire ranking, all rows get the highest rank within the sharing group.</p> <p>If ranks within the sharing group span over the middle value of the entire ranking, all rows get the value corresponding to the average of the top and bottom ranking in the entire partition.</p> |

| Value | Description                                                     |
|-------|-----------------------------------------------------------------|
| 1     | Lowest rank on all rows.                                        |
| 2     | Average rank on all rows.                                       |
| 3     | Highest rank on all rows.                                       |
| 4     | Lowest rank on first row, then incremented by one for each row. |

### fmt

The second argument, **fmt**, can take the following values:

#### fmt values

| Value       | Description                                             |
|-------------|---------------------------------------------------------|
| 0 (default) | Low value - high value on all rows (for example 3 - 4). |
| 1           | Low value on all rows.                                  |
| 2           | Low value on first row, blank on the following rows.    |

The order of rows for **mode 4** and **fmt 2** is determined by the load order of the table fields.

### Example - Adding a ranked field with multiple partitions

Example: Adding a ranked field with multiple partitions

#### Load script

Create a new tab in the data load editor, and then load the following data as an inline load. Create the table below in Qlik Sense to see the results.

Transactions:

Load

```
*,window(wRank(0,1),customer_id, size, color_code, 'Desc', transaction_amount) as
TransactionRanking;
```

Load \* Inline [

```
transaction_id, transaction_date, transaction_amount, transaction_quantity, customer_id, size,
color_code
```

```
3750, 20180830, 23.56, 2, 2038593, L, Red
3751, 20180907, 556.31, 6, 203521, M, Orange
3752, 20180916, 5.75, 1, 5646471, S, Blue
3753, 20180922, 125.00, 7, 3036491, L, Black
3754, 20180922, 484.21, 13, 049681, XS, Red
3756, 20180922, 59.18, 2, 2038593, M, Blue
3757, 20180923, 177.42, 21, 203521, XL, Black
3758, 20180924, 153.42, 14, 2038593, L, Red
3759, 20180925, 7.42, 5, 203521, M, Orange
3760, 20180925, 80.12, 18, 5646471, M, Blue
3761, 20180926, 3.42, 7, 3036491, XS, Black
3763, 20180926, 63.55, 12, 049681, S, Red
3763, 20180927, 177.56, 10, 2038593, L, Blue
3764, 20180927, 325.95, 8, 203521, XL, Black
];
```

#### Results

Results for adding a ranked field using fmt for a single digit result

| transaction_id | transaction_date | transaction_amount | transaction_quantity | customer_id | size | color_code | TransactionRanking |
|----------------|------------------|--------------------|----------------------|-------------|------|------------|--------------------|
| 3750           | 20180830         | 23.56              | 2                    | 2038593     | L    | Red        | 2                  |
| 3751           | 20180907         | 556.31             | 6                    | 203521      | M    | Orange     | 1                  |
| 3752           | 20180916         | 5.75               | 1                    | 5646471     | S    | Blue       | 1                  |
| 3754           | 20180922         | 484.21             | 13                   | 049681      | XS   | Red        | 1                  |
| 3756           | 20180922         | 59.18              | 2                    | 2038593     | M    | Blue       | 1                  |
| 3753           | 20180922         | 125.00             | 7                    | 3036491     | L    | Black      | 1                  |

| transaction_id | transaction_date | transaction_amount | transaction_quantity | customer_id | size | color_code | TransactionRanking |
|----------------|------------------|--------------------|----------------------|-------------|------|------------|--------------------|
| 3757           | 20180923         | 177.42             | 21                   | 203521      | XL   | Black      | 2                  |
| 3758           | 20180924         | 153.42             | 14                   | 2038593     | L    | Red        | 1                  |
| 3759           | 20180925         | 7.42               | 5                    | 203521      | M    | Orange     | 2                  |
| 3760           | 20180925         | 80.12              | 18                   | 5646471     | M    | Blue       | 1                  |
| 3763           | 20180926         | 63.55              | 12                   | 049681      | S    | Red        | 1                  |
| 3761           | 20180926         | 3.42               | 7                    | 3036491     | XS   | Black      | 1                  |
| 3764           | 20180927         | 325.95             | 8                    | 203521      | XL   | Black      | 1                  |
| 3763           | 20180927         | 177.56             | 10                   | 2038593     | L    | Blue       | 1                  |

### Limitations

WRank has the following limitations:

- If your fmt value is 0 and you want to use the text part of the dual result for **WRank**, you must use **Text()** with **Window(WRank)**. For example: `Text(Window(WRank(0), unit, 'DESC', Age)) as unitWRankedByAgeText`.

## 10 Security

A security mechanism in QlikView can be set up in two different ways: It can either be built into the QlikView document script, or it can be set up through the use of QlikView Publisher.

### 10.1 Authentication and Authorization

Authentication is any process by which it is verified that someone is who they claim they are. QlikView can either let the Windows operating system do the authentication, or prompt for a User ID and Password (different from the Windows User ID and Password) or use the QlikView license key as a simple authentication method.

Authorization is finding out if the person, once identified, is permitted to have the resource. QlikView can either let the Windows operating system do the authorization or do the authorization itself. For the latter, a security table must be built into the script.

### 10.2 Security Using the QlikView Publisher

If the QlikView Publisher is set up to handle security, then each QlikView file will be split up into several files, each containing the data pertaining to the relevant user or user group. These files will be stored in folders with the correct OS security settings, that is, QlikView lets the operating system handle Authentication and Authorization.

There is, however, no security built into the file itself, so there is no protection on a downloaded file.

The file sizes will usually be smaller, since one single file will be split into several and the user only opens the file with his own data. However, this also means that a QlikView Server can potentially use more memory than if all data are kept in one file, since several files containing the same data sometimes will be loaded.

For further information, see the QlikView Publisher documentation.

### 10.3 Security Using the Section Access in the QlikView Script

If the Section Access in the QlikView script is set up to handle security, then one single file can be made to hold the data for a number of users or user groups. QlikView will use the information in the Section Access for Authentication and Authorization and dynamically reduce the data, so that the user only sees his own data.

The security is built into the file itself, so also a downloaded file is to some extent protected. However, if the security demands are high, downloads of files and offline use should be prevented. The files should be published by the QlikView Server only.

Since all data are kept in one file, the size of this file can potentially be very large.

QlikView documents can be made invisible in offline mode. To make an offline user document invisible, add the following attribute in the document information section of a user document using the QMC:

- Name: *Invisible*
- Value: *True*

All information below refers to the security method of using Section Access in the QlikView script.

## 10.4 Sections in the Script

Row-level access is managed through one or several security tables loaded in the same way as data is normally loaded. This makes it possible to store these tables in a standard database or in a spreadsheet. The script statements managing the security tables are given within an authorization section, which in the script is initiated by the statement **Section Access**.

If an authorization section is defined in the script, the part of the script loading the app data must be put in a different section, initiated by the statement **Section Application**.

**Example:**

```
Section Access;
AuthorizationTable:
Load ACCESS, USERID, REGION From ...;

Section Application;
Load ... From ...;
```

## 10.5 Access Levels in Section Access

Access to QlikView documents can be authorized for specified users or groups of users. In the security table, users can be assigned to the access levels ADMIN or USER. If no access level is assigned, the user cannot open the QlikView document.

A person with ADMIN access can change everything in the document. Using the **Security** page in the **Document Properties** and **Sheet Properties** dialogs, a person with ADMIN access can limit the users' possibilities of modifying the document. A person with USER privileges cannot access the **Security** pages.

*ADMIN rights are only relevant for local documents! Documents opened on a Server are always accessed with USER rights.*

## 10.6 Section Access System Fields

The access levels are assigned to users in one or several tables loaded within the section access. These tables can contain several different user-specific system fields, typically USERID and PASSWORD, and the field defining the access level, ACCESS. All **Section Access** system fields will be used for authentication or authorization. The full set of **section access** system fields are described below.

None, all, or any combination of the security fields may be loaded in the access section. It is thus not necessary to use USERID - an authorization can be made using other fields, for example, serial number only.

## Section Access system fields

| Field       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACCESS      | A field that defines what access the corresponding user should have.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| USERID      | A field that should contain an accepted user ID. QlikView will prompt for a User ID and compare it to the value in this field. This user ID is not the same as the Windows user ID.                                                                                                                                                                                                                                                                                                                                                   |
| USER.EMAIL  | Currently not supported, will in QlikView only match on wildcard.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| PASSWORD    | A field that should contain an accepted password. QlikView will prompt for a Password and compare it to the value in this field. This password is not the same as the Windows password.                                                                                                                                                                                                                                                                                                                                               |
| SERIAL      | A field that should contain a number corresponding to the QlikView serial number or the string 'QLIKVIEW'.<br>Example: 4900 2394 7113 7304<br>QlikView will check the serial number of the user or the string 'QLIKVIEW' and compare it to the value in this field.                                                                                                                                                                                                                                                                   |
| NTNAME      | A field that should contain a string corresponding to a Windows NT Domain user name or group name. If a different authentication system is used, it should contain the name of an authenticated user.<br>QlikView will fetch the logon information from the OS and compare it to the value in this field.                                                                                                                                                                                                                             |
| NTDOMAINSID | A field that should contain a string corresponding to a Windows NT Domain SID.<br>Example: S-1-5-21-125976590-4672381061092489882<br>QlikView will fetch the logon information from the OS and compare it to the value in this field.                                                                                                                                                                                                                                                                                                 |
| NTSID       | A field that should contain a Windows NT SID.<br>Example: S-15-21-125976590-467238106-1092489882-1378<br>QlikView will fetch the logon information from the OS and compare it to the value in this field.                                                                                                                                                                                                                                                                                                                             |
| OMIT        | A field that should contain the field that should be omitted for this specific user. Wildcards may be used and the field may be empty. A facile way of doing this is to use a subfield.<br><br><div style="border: 1px solid black; padding: 10px; margin-top: 10px;">  <i>You should not apply OMIT on key fields, as this will change the underlying data structure. This may create logical islands and calculation inconsistencies.</i> </div> |

QlikView will compare the QlikView serial number with the field *SERIAL*, the Windows NT User name and groups with *NTNAME*, the Windows NT Domain SID with *NTDOMAINSID* and the Windows NT SID with *NTSID*. It will further prompt for User ID and Password and compare these with the fields *USERID* and *PASSWORD*.

If the found combination of user ID, password and environment properties is also found in the **section access** table, then the document is opened with the corresponding access level. If not, QlikView will deny the user access to the document. If the User ID and/or the Password are not entered correctly within three attempts the entire log-on procedure must be repeated.

Since the same internal logic that is the hallmark of QlikView is used also in the access section, the security fields may be put in different tables. (It is thus possible for a system manager to make a QlikView document out of the security tables. In this case a correct serial number, password etc. is simulated by a click on the corresponding field value.)

In the logon procedure, QlikView will first check *SERIAL*, *NTNAME*, *NTDOMAINSID* and *NTSID* to see if this information is enough to grant the user access to the document. If so, QlikView will open the document without prompting for User ID and Password.

If only some of the access fields are loaded, the appropriate of the above requirements are used.

All the fields listed in **Load** or **Select** statements in the section access must be written in UPPER CASE. Any field name containing lower case letters in the database should be converted to upper case using the **upper** function before being read by the **Load** or **Select** statement.

*Upper (page 1562)*

However the user ID and the password entered by the end-user opening the QlikView documents are case insensitive.

A wildcard (\*) is interpreted as all (listed) values of this field, that is, a value listed elsewhere in this table. If used in one of the system fields (*USERID*, *PASSWORD*, *NTNAME* or *SERIAL*) in a table loaded in the access section of the script, it is interpreted as all (also not listed) possible values of this field.

*When loading data from a QVD file, the use of the upper function will slow down the loading speed.*

*To generate access tables in inline statements use the **Access Restriction Table Wizard**.*

*If you have enabled section access, you cannot use the section access system field names listed here as field names in your data model.*

### Example 1:

Only serial number is checked. One specific computer gets ADMIN access. Everyone else gets USER access. Note that a star can be used to mark “any serial number”.

Example 1

| ACCESS | SERIAL              |
|--------|---------------------|
| ADMIN  | 4900 2394 7113 7304 |
| USER   | *                   |

**Example 2:**

The administrator and the server on which QlikView runs as a batch job get ADMIN access. Everyone else in the Domain gets USER access when entering "USER" as user ID and password.

Example 2

| ACCESS | SERIAL              | NTDOMAINSID                             | USERID | PASSWORD |
|--------|---------------------|-----------------------------------------|--------|----------|
| ADMIN  | *                   | S-1-5-21-125976590-467238106-1092489882 | ADMIN  | ADMIN    |
| ADMIN  | 4900 2394 7113 7304 | *                                       | *      | *        |
| USER   | *                   | S-1-5-21-125976590-467238106-1092489882 | USER   | USER     |

## 10.7 Mixed environments

If you plan to use the same authorization table in both QlikView and Qlik Sense SaaS, there are a couple of things to be aware of:

- USERID has different meanings in QlikView and Qlik Sense SaaS, and could, if used, cause security problems. Use NTNAME instead or combine it with SERIAL as described below.
- GROUP and fields beginning with 'USER.', such as 'USER.NAME' and 'USER.EMAIL', etc. are (or will be) authenticating fields in Qlik Sense Enterprise SaaS. If you use these fields in your Section Access, access may be denied in Qlik Sense SaaS.
- PASSWORD, NTSID and NTDOMAINSID cannot be used in Qlik Sense SaaS. Access will be denied, unless a wildcard is used.
- SERIAL cannot be used to check license number in Qlik Sense SaaS. However, if this field contains the string 'QLIKCLOUD' or 'QLIKVIEW', access might be granted. This means that it is possible to have an authorization table like the following, where line 1 will grant access in QlikView (but not in Qlik Sense SaaS), and line 2 will grant access in Qlik Sense SaaS (but not in QlikView).

| Line | SERIAL              | USERID   | Comment                                                      |
|------|---------------------|----------|--------------------------------------------------------------|
| 1    | 4600 0123 4567 8901 | *        | Grants access to correct license number in QlikView.         |
| 2    | QLIKCLOUD           | John Doe | Grants access to correct user in Qlik Sense Enterprise SaaS. |

| Line | SERIAL    | USERID   | Comment                                                      |
|------|-----------|----------|--------------------------------------------------------------|
| 1    | QLIKVIEW  | *        | Grants access to QlikView.                                   |
| 2    | QLIKCLOUD | John Doe | Grants access to correct user in Qlik Sense Enterprise SaaS. |

## 10.8 Restrictions on QlikView Functionality

The controls found on the **Document Properties: Security** page and the **Sheet Properties: Security** page make it possible to disallow the access to certain menu items and prohibit changes in the layout. If these settings are to be used as a truly protective measure, it is important that the document users are logged in as USER. Anyone logged in as ADMIN can change the security settings at any time.

A user that has opened the document with USER rights does not have the **Security** pages in the Properties dialogs.

## 10.9 Dynamic Data Reduction

QlikView and QlikView Server support a feature by which some of the data in a document can be hidden from the user based on the **section access** login.

First of all, fields (columns) can be hidden by the use of the system field **OMIT**.

Secondly, records (rows) can be hidden by linking the **Section Access** data with the real data: The selection of values to be shown/excluded is controlled by means of having one or more fields with common names in **section access** and **section application**. After user login QlikView will attempt to copy the selections in fields in **section access** to any fields in **section application** with exactly the same field names (the field names must be written in UPPER CASE). After the selections have been made, QlikView will permanently hide all data excluded by these selections from the user.

In order for this procedure to take place, the option **Initial Data Reduction Based on Section Access** on the **Document Properties: Opening** page must be selected. If this feature is used in documents that are to be distributed by other means than via QlikView Server, the option **Prohibit Binary Load** on the same page of the Document Properties must be selected in order to maintain data protection.

*All field names used in the transfer described above and all field values in these fields must be upper case, since all field names and field values are by default converted to upper case in **section access**.*

### Example:

```
section access;
LOAD * inline [
ACCESS, USERID, REDUCTION, OMIT
ADMIN, ADMIN, *,
USER, A, 1
USER, B, 2, NUM
```

```
USER, C, 3, ALPHA
];
section application;
T1:
LOAD *,
NUM AS REDUCTION;
LOAD
Chr(RecNo()+ord('A')-1) AS ALPHA,
RecNo() AS NUM
AUTOGENERATE 3;
```

The field REDUCTION (upper case) now exists in both **section access** and **section application** (all field values are also upper case). The two fields would normally be totally different and separated, but if the **Initial Data Reduction Based on Section Access** option has been selected, they will link and reduce the number of records displayed to the user.

The field OMIT in **section access** defines the fields that should be hidden from the user.

The result will be as follows:

User A can see all fields, but only those records connected to REDUCTION=1.

User B can see all fields except NUM, and only those records connected to REDUCTION=2.

User C can see all fields except ALPHA, and only those records connected to REDUCTION=3.

## 10.10 Inherited Access Restrictions

A binary load will cause the access restrictions to be inherited by the new QlikView document. A person with ADMIN rights to this new document may change the access rights of this new document by adding a new **access** section. A person with USER rights can execute the script and change the script, thus adding own data to the binary loaded file. A person with USER rights cannot change the access rights. This makes it possible for a database administrator to control the user access also to binary loaded QlikView documents.

## 10.11 Encryption

The communication between a QlikView Server and a QlikView Windows client is encrypted. If, however, the AJAX client is used, the communication is not encrypted.

In addition, all QlikView documents are scrambled which makes the information unreadable with viewers, debuggers etc.

You can also encrypt sensitive data in QVD files with customer supplied key pairs which allows you to control who gets access to your data.

# 11 AJAX/WebView

This guide is used for the AJAX client as well as the WebView mode in the QlikView Desktop. Some features might differ slightly in the different clients.

## 11.1 WebView Mode in QlikView Desktop

Via a single click on a toolbar button it is now possible to switch between traditional rendering and AJAX rendering when running QlikView Desktop. This feature provides a convenient way for the developer to see exactly how the layout will look when used from an AJAX client. Naturally the AJAX property dialogs are available when running in WebView, providing some nice functionality that is not available to the developer in standard view. However, it should be noted that some functionality are not available in WebView, for example:

- Report editing.
- Menu commands cut, copy, and paste (shortcuts Ctrl+X, Ctrl+C, and Ctrl+V).
- Animation of charts.
- Printing or exporting embedded images.

## 11.2 Copying Chart Images to Clipboard

It is possible to copy images of chart objects to clipboard by holding down Ctrl+Shift and right clicking on the chart object, then selecting Copy from the menu.

## 11.3 Touch Functionality

The following functionality is supported on touch screens:

- Creating objects
- Moving, copying and resizing objects
- Changing properties

## 11.4 File Name Limitations

If you want to share a QlikView document using AJAX clients, the file name must not contain hash (#) characters.

## 11.5 Keyboard Shortcuts

QlikView Desktop keyboard shortcuts are not available in the AJAX client.

## 11.6 AJAX on Small Devices

AJAX on Small Devices creates support for QlikView data exploration on small form touch devices, such as smart phones. Existing applications may be used without redesigning, as QlikView features are used along with built-in scrolling and zooming functionality in the small device. It is possible to open the QlikView document in a layout that automatically redesigns objects to suit small devices, or in its original application layout. Unlike in the Ajax client, Small device version does not have sheet concept, therefore loads all objects. Please avoid to develop large document for Small device version.

The following descriptions are made using an iPhone, and may vary slightly when using other small devices.

### Preparations for AJAX on Small Devices

#### Connecting to the QlikView Document

You can select all QlikView documents available to you from QlikView AccessPoint. Connection to QlikView AccessPoint is done by typing `http://localhost/qlikview/index.htm` in the web browser.

#### Settings in QlikView AccessPoint

Set the preferred mobile version on the QlikView AccessPoint start page:

QlikView platform versions

| Version              | Details                                                                                             |
|----------------------|-----------------------------------------------------------------------------------------------------|
| Small Device Version | Shows the QlikView document in a layout that automatically redesigns objects to suit small devices. |
| Ajax client          | Shows the QlikView document in original application layout.                                         |

Also select if the setting is to be saved for the device. The setting may be edited later, by selecting **Favorites & Profiles** at the top right-hand corner of the QlikView AccessPoint start page, on the **Profile** tab.

It is possible to switch between the different layouts at any time, when the QlikView document is opened.

#### Creating a Shortcut on the Home Screen

Once the QlikView document is opened, it is possible to create a shortcut to the document from the **Home** screen. This maximizes work space for the QlikView document, rather than displaying the browser address field. After having created the shortcut, tap the icon to relaunch the application.

*This description applies only when using an iPad or an iPhone.*

### Working with QlikView documents on Small Devices

#### Adapted Layout

In order to use the limited space of the small device in an optimized way, some objects are not included when opening the document using AJAX on Small Devices:

- Button
- Container
- Line Arrow
- Current Selections Box
- Input Box
- Multi Box
- Bookmark Object
- Search Object
- Text Object

Access to the excluded objects is available by switching to Ajax client.

#### Navigating Among Sheets

To navigate between sheets, drag your finger up or down on the screen (vertical scrolling).

#### Navigating Among Objects

To navigate between objects of the current sheet from the document start screen, drag your finger right or left on the screen (horizontal scrolling). To select an object, press it with your finger.

To navigate to the next object on the sheet when an object has been selected, flick left or right, or tap to the left or right of the row of dots at the bottom of the screen.

## Main Menu

The main menu is located at the bottom of the screen when a QlikView document is opened, and contains a number of options:

## Current Selections

Pressing **Current Selections** displays selections that are currently made, and any already made selections can be edited or removed. The current selections affect what is displayed in all objects in the QlikView document. Pressing the arrow in the top right-hand corner opens the **Current Selections** menu, with the following options:

## Current Selections options

| Option          | Description                                                                                                                                                                         |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Back            | Reverts to the preceding selection state.                                                                                                                                           |
| Forward         | Reverts to the selection state before having selected <b>Back</b> . It is possible to toggle between two states by alternating between the <b>Back</b> and <b>Forward</b> commands. |
| Lock all fields | Locks all selected values.                                                                                                                                                          |

| Option               | Description                                |
|----------------------|--------------------------------------------|
| Unlock all fields    | Unlocks all currently locked values.       |
| Clear all selections | Clears all selections, except locked ones. |
| Unlock and clear all | Unlocks and clears all values.             |

### Bookmarks

Pressing **Bookmarks** displays all bookmarks that are defined for the document. The current state of selections can be saved as bookmarks for later use. Bookmarks capture selections in all states defined in a QlikView document. When recalling a bookmark, the selections in all states will be applied. Bookmarks cannot be defined, only viewed, when using the layout adapted for small devices.

### Switch to Ajax Client

When having opened the QlikView document in the version optimized for small devices, it is possible to switch to original application layout by selecting the **Switch to Ajax Client** option.

### Close [Current Document]

Closes the current document.

### Working with Objects

To select a part of the displayed values in for example a bar chart, or to select multiple lines in a line chart, hold your finger on the object until the resizable selection area pops up. Resize the selection area according to your preference, and press the **Select** button at the top left-hand corner.

The selected values are now displayed.

When a menu is available, it is accessed by pressing the arrow at the top right-hand corner. When an object is selected, the menu includes **Current Selections** and **Bookmarks**. The menu is closed by pressing the X-icon.

To return to the previous view, press the **Back** icon at the top left-hand corner.

To select multiple items in a list box or in a table, hold your finger on the item until the **Select**, **Clear** and **Cancel** buttons are displayed at the top of the screen. Use the **Select** button to add selections, and **Clear** buttons to remove selections.

## Orientation and Zooming

Rotating the small device 90° allows working with the QlikView document in landscape orientation.

Zooming of QlikView objects is supported when having opened the document in Ajax client, using the regular zooming functionality of the small device.

## 11.7 Setting your preferred language in AccessPoint

By default, QlikView WebView uses the language selected during installation while AJAX uses English for both AccessPoint and QlikView documents. You can change your language setting in QlikView AccessPoint to another language. Your language selection is saved in a cookie for one year. For a full list of the supported languages, see *Supported languages (page 32)*

*If you clear your browser's cookies, you must set your language again. If you use multiple browsers, you must set your language preference in AccessPoint in each browser that you use.*

*If you have any QlikView documents open when you change your language in AccessPoint, the language will not change until they are closed and reopened.*

Do the following:

1. Log into AccessPoint.
2. Click **Favorites & profile**.
3. Click the **Profile** tab.
4. Select a language from the **Preferred language** drop-down.

AccessPoint will refresh and display in the selected language.

## 11.8 NPrinting On-Demand

You can create reports based on Qlik NPrinting templates by using the On-Demand feature available in the QlikView WebView interface. For more information about installing the On-Demand Add-on and creating On-Demand reports, see the following section:

≤ [On-Demand reports](#)

### Create a Qlik NPrinting report in QlikView

1. In the QlikView WebView interface, click the **On-Demand** button in the toolbar.  
The **Qlik Nprinting** window opens.
2. Click **Create a report**.
3. Click a report to select the Qlik NPrinting report template that you want to use.
4. Select an export format for the report.
5. Click **Generate report**.

The report status will be listed as **In queue**. When the report is complete, you can download a copy to your computer.

## 11.9 Sheet

A QlikView document can have one or several sheets on which the sheet objects are placed. Each sheet can contain many sheet objects. The sheets have no connection with the logic - if two fields are logically connected, it does not matter if they are put on the same sheet or on different sheets. The logical result when making selections will still be the same.

*Depending on whether you are running WebView or AJAX, some of these settings may not be available.*

### Sheet: Object Menu

Sheet: Object Menu properties

| Property              | Details                                                                                                                                |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| Properties...         | Opens the sheet's <b>Properties</b> dialog.                                                                                            |
| New Sheet Object      | Opens a dialog, from which you can drag a sheet object onto the sheet.                                                                 |
| Select Fields...      | Opens the <b>Fields</b> dialog. Here you can select the fields to be displayed on the current sheet.                                   |
| Clear                 | Clicking on this button applies the start selection of a QlikView document, which can be configured, see <b>Set Clear State</b> below. |
| Clear All Selections  | Deselects all the selected values of the document.                                                                                     |
| Set Clear State       | Sets the current selection as <b>Clear State</b> .                                                                                     |
| Reset Clear State     | Resets Clear State to no selections.                                                                                                   |
| Back                  | QlikView remembers the last 100 selections. By clicking this button, you go one step back in the list of selections.                   |
| Forward               | By clicking <b>Forward</b> , you go one step forward in the list of selections (equivalent to canceling the last <b>Back</b> command). |
| Undo Layout           | Undoes the last layout action.                                                                                                         |
| Redo Layout           | Redoes the latest undone layout action.                                                                                                |
| Lock All Selections   | Prevents selections from being cleared by mistake.                                                                                     |
| Unlock All Selections | Takes away the lock described above.                                                                                                   |

| Property                   | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Selections                 | Opens a <b>Current Selections</b> box in which it is possible to see the selections that are active.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Add Sheet                  | Adds a new sheet to the document.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Paste Sheet Object         | Pastes a sheet object which has previously been put on the clipboard via the <b>Cut</b> or <b>Copy</b> commands within the QlikView document.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Create Quick Chart...      | Opens the <b>Quick Chart Wizard</b> where you can create bar, line and pie charts with only very basic settings.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Repository...              | Opens the <b>Repository</b> dialog.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Add Bookmark               | Saves the current set of selections as a bookmark.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Remove Bookmark            | Opens a drop-down list showing all bookmarks in the document. Here you can choose which bookmark to remove.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Mail with Bookmark as Link | Creates an e-mail with a URL link to the current server document. A temporary server bookmark will be created (including layout state) and encoded in the URL. The mail recipient will be able to use the URL link to open the server document and see what you see, provided that he has access rights to the document and its data.<br><br><b>Limitations:</b> <ul style="list-style-type: none"> <li>• An e-mail client has to be configured for this command to work.</li> <li>• The QlikView Server must be configured to allow server bookmarks.</li> <li>• This feature is not supported in extranet deployments.</li> </ul> |
| Delete                     | Deletes the selected item.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Refresh                    | Refreshes the QlikView document.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## 11.10 Toolbar

The toolbar at the top in the web browser window contains the following icons:

Toolbar icons

| Icon                                                                                | Description                                                                                                      |
|-------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
|  | Returns you to AccessPoint.                                                                                      |
|  | Applies the start selection of the QlikView document.                                                            |
|  | Moves one step back in the list of selections.                                                                   |
|  | Moves one step forward in the list of selections, provided that you have previously used the <b>Back</b> button. |

| Icon                                                                                | Description                                                                                                                                                                                         |
|-------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|    | Undoes the last layout action.                                                                                                                                                                      |
|    | Redoes the latest undone layout action.                                                                                                                                                             |
|    | Locks all the selected cells.                                                                                                                                                                       |
|    | Unlocks all the locked cells.                                                                                                                                                                       |
|    | Opens the current selections window.                                                                                                                                                                |
|    | Opens the <i>Notes and Comments</i> window where you can view notes.                                                                                                                                |
|    | Opens the <b>Repository</b> dialog.                                                                                                                                                                 |
|    | Opens the <b>New Sheet Object</b> dialog where you can choose an object to drag to the sheet.                                                                                                       |
|    | Opens the <b>Fields</b> dialog.                                                                                                                                                                     |
|   | Opens the <b>Add Bookmark</b> dialog. In order to access a shared bookmark, it has to be added from the repository. From the repository, select <b>Edit</b> and check <b>Show in my favorites</b> . |
|  | Opens a list of all bookmarks in the document. Select a bookmark to delete it.                                                                                                                      |
|  | The drop-down contains a list of all bookmarks in the document. Bookmarks can be searched by name or selected from the drop-down.                                                                   |
|  | The drop-down contains a list of all reports in the document. Reports can be searched by name or selected from the drop-down.                                                                       |
|  | Opens help.                                                                                                                                                                                         |

## 11.11 Repository

In this dialog you see a list of the objects, dimensions, expressions and bookmarks that the document contains. With objects and bookmarks you can filter and sort the list using the two drop-down boxes at the top.

## Filter Options (Objects and Bookmarks)

Filter Options (Objects and Bookmarks)

| Option                             | Description                                                                                                                                                       |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Show items created by me (default) | Show only objects or bookmarks that you have created as user items on the server.                                                                                 |
| Show shared items                  | Show only objects or bookmarks that have been shared by another user.                                                                                             |
| Show document items                | Show only objects or bookmarks that are created in the QlikView document. Items created in WebView developer mode of QlikView are also considered document items. |
| Show all items                     | Show all objects or bookmarks.                                                                                                                                    |

## Sort Options (Objects and Bookmarks)

You can sort the list by name, type, owner or date.

### Objects

A list of all the objects of the document. Click and drag an object from the list onto the sheet to create a copy of the object. Clicking  opens the properties dialog for the object. Click  to remove all instances of the object from the document. The question mark at the top of the list opens a small help dialog.

### Dimensions

A list of all the dimensions that are used in the document. From here you can drag a dimension to an existing object and change the existing dimensions, add it as a new dimension, change an expression or add it as a new expression.

### Expression

A list of all the expressions that are used in the document. From here you can drag a dimension to an existing object and change the existing dimensions, add it as a new dimension, change an expression or add it as a new expression.

### Bookmarks

A list of all the bookmarks that are used in the document. Click on one of the bookmarks to apply it. Clicking  opens the properties dialog for the object. Click  to remove all instances of the object from the document. The question mark at the top of the list opens a small help dialog. In order to access a shared bookmark, it has to be added from the Repository. From the Repository, select **Edit** and check **Show**.

## 11.12 List Box - AJAX/Webview

This is the most basic object on the screen. It contains a list of all the possible values of a specific field. In a list box you often make selections, and look at logical connections and implications.

A list box may also contain a cyclic or drill-down group. If a drill-down group is used, selecting a single value in the list box will cause the list box to drill down and switch to the next underlying field in the group. Drilling back up can be accomplished by clicking the drill-up icon in the list box caption.

If a cyclic group is assigned to a list box it can be made to show the next field in the group by clicking on the cycle icon that appears in the list box caption. It is also possible to go directly to any field in the group by using the **Cycle->** option on the list box object menu.

### List Box: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

List Box: Object Menu commands

| Command            | Details                                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Properties...      | Opens the <b>Properties</b> dialog for the active sheet object.                                                                                                                                                                     |
| Notes              | Allows creating and sharing notes about the current object.                                                                                                                                                                         |
| Search             | Opens the text search box.                                                                                                                                                                                                          |
| Fuzzy Search       | Opens the text search in fuzzy search mode.                                                                                                                                                                                         |
| Select Possible    | All non-excluded values in the sheet object are selected.                                                                                                                                                                           |
| Select Excluded    | All excluded values in the sheet object are selected.                                                                                                                                                                               |
| Select All         | All values in the sheet object are selected.                                                                                                                                                                                        |
| Clear              | Clears all the current selections in the active sheet object. Clicking on the  icon in the object caption (if shown) produces the same result. |
| Clear Other Fields | Clears the selections in all the other sheet objects, while maintaining the ones in the currently active sheet object.                                                                                                              |
| Lock               | Locks the selected value(s) in the active sheet object. (Unavailable if no selections have been made).                                                                                                                              |
| Unlock             | Unlocks the locked value(s) in the active sheet object. (Appears instead of <b>Lock</b> if selections have been locked).                                                                                                            |

| Command                      | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Copy                         | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                                                                                                 |
| Copy cell value to clipboard | Copies the selected cell value to the clipboard.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Copy selections to clipboard | Copies the list box selections to the clipboard.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Print...                     | Opens the selected sheet object(s) in tabular format in another browser window.<br><br>Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                           |
| Send to Excel                | Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Clicking on the  icon in the object caption (if shown) produces the same result. |
| Export...                    | Opens the <b>Save as</b> dialog where path, file name and (table) file type for the exported data content can be specified.                                                                                                                                                                                                                                                                                                                                        |
| Delete                       | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                                                                                                                                                        |

## List Box Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

### Field

Select a field in the drop-down.

For more information click the **More...** button.

### Sort

Sets the sort order of the values in the sheet object. Some sort options may not be available for all sheet objects.

If more than one sort order is specified, the sort order will be state, expression, frequency, numeric, text, load order. **State** refers to the logical state (selected, optional, or excluded).

- **Primary Sort: Y-Value:** Sets whether the dimension values should be sorted according to the numeric value of the y-axis. This option is not available for calculated dimensions. **Frequency:** Sorts the field values by frequency (number of concurrences in the table). **Numeric Value:** Sorts the field values by their numeric values. **Text:** Sorts the field values in alphabetical order. **Load Order:** Sorts the field values by the initial load order.

- **Secondary Sort: Frequency:** Sorts the field values by frequency (number of concurrences in the table).  
**Numeric Value:** Sorts the field values by their numeric values.  
**Text:** Sorts the field values in alphabetical order.  
**Load Order:** Sorts the field values by the initial load order.
  - **Sort by Expression:** Sorts the field values according to the expression entered. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Keep Selected on Top:** Enable this to keep the selected on top.

## Number

Each field has a default number format which can be set in the Document Properties: Number page. It is however possible to use a separate number format for an individual sheet object. This property page applies to the active object and contains the following controls for formatting values:

- **Override Default Settings:** Select to override the default settings for the active object. Number Format Choose a number format from the alternatives below.
  - **Mixed:** Both numbers and text. Numbers are shown in original format.
  - **Number:** Shows numeric values with the number of digits set in the **Precision** field.
  - **Integer:** Shows numeric values as integers.
  - **Fixed to:** Shows numeric values as decimal values with the number of decimal digits set in the **Decimals** field.
  - **Money:** Shows values in the format set in the **Format Pattern** field. The default format is the Windows Currency setting.
  - **Date:** Shows values that can be interpreted as dates in the format set in the **Format Pattern** field.
  - **Time:** Shows values that can be interpreted as time in the format set in the **Format Pattern** field.
  - **Timestamp:** Shows values that can be interpreted as date + time in the format set in the **Format Pattern** field.
  - **Interval:** Shows time as sequential time increments (e.g. format = mm shows the value as the number of minutes since calendar start ( 1899:12:30:24:00)).
- **Format Pattern:** The format code that further specifies the display format of the field. **ISO** sets the format to the ISO standard. Only valid for **Date**, **Time**, **Timestamp** and **Interval**. **Sys** sets the format to the system settings.
- **Precision:** The number of digits that will be displayed.
- **Decimals:** Sets the number of decimals included.
- **Decimals Separator:** Sets the symbol for decimal separators.
- **Thousand Separator:** Sets the symbol for thousand separators.
- **In Percent:** Shows formatting in percentage instead of absolute numbers. The setting is only available for **Number**, **Integer** and **Fixed to**.
- **Preview:** Shows a preview of the number format specified above.

## Hide Excluded

Toggles whether the excluded values of the field should be shown or not. Excluded values become unselectable as well.

## Override Locked Field

Checking this option enables selections to be made in the sheet object even if it is locked. The sheet object will still be locked for selections made elsewhere in the document.

## Show Frequency

Toggles the status for whether the frequency of a field value is shown or not. By frequency is meant the number of selectable combinations in which the value occurs. This option is not available for calculated fields.

## In Percent

Toggles the status for whether the frequency should be shown in absolute numbers or as percentages of the total number of entries.

## Expressions

To add an expression click . Choose expression in the list. The  icon moves the items in the list.

The  icon removes items from the list. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog. Click  to open the **Expression Settings** dialog.

## Enable

Marking this check box will enable the selected expression. If the box is not marked, the expression will not be used at all.

## Conditional

The column will be displayed or hidden depending on a condition expression which will be evaluated each time the object is drawn. The value may be entered as a calculated formula.

## Expression

Enter the expression you wish to display. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.

## Data (Numeric)

Sets the alignment for numeric data to **Left**, **Centered** or **Right**.

## Data (Text)

Sets the alignment for text data to **Left**, **Centered** or **Right**.

## Representation

Choose a representation in the drop-down list. Depending on which representation is chosen different settings are shown.

- **Text:** No other settings.
- **Image:**
- **No Stretch:** When **Image** is selected, settings can be made for **Image Stretch**:
  - **No Stretch:** Displays the image without stretching. This may cause parts of the picture to be invisible or only part of the object to be filled.
  - **Fill:** The image is stretched to fit the object area without keeping the aspect ratio of the image.
  - **Keep Aspect:** The image is stretched as far as possible to fill the object area while keeping the aspect ratio.
  - **Fill with Aspect:** The image is stretched to fill the object area in both directions while keeping the aspect ratio.
- **Gauge:** Different gauge styles are available. The gauge chart will be inscribed in the available table cell. Settings for the different gauge alternatives:
  - **Min:** Specifies the minimum value of the gauge. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
  - **Max:** Specifies the maximum value of the gauge. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
  - **Mini Chart:** When selecting this option, QlikView will display the expression value in a miniature chart with the expression aggregated over an extra dimension. The chart will be inscribed in the available table cell. The mini chart dimension can be defined as well as visual settings. Settings for the Mini Chart:
    - **Field:** Choose the field for which the expression should be plotted.
    - **Mode:** Set the mini chart as sparklines, lines, dots, bars or whiskers.

*The mini chart will not be displayed when exporting to Excel!*

## List Box Properties: Presentation

### Presentation

**Selection Style** Sets the selection style for the document. Select between the available alternatives in the drop-down menu. By choosing **<User Default>** the document will always be opened with the selection style set as preferred by the user under **User Preferences** on the computer where it is opened.

- **Representation:** This section describes **Representation** options.
  - **Text:** When selecting this option, the field values will always be interpreted and displayed as text.
  - **Image:** When selecting this option QlikView will try to interpret each field value as a reference to an image. The reference may be a path to an image file on disk (e.g.

C:\Mypic.png) or inside the QlikView document (e.g. qmem://<Name>/<Peter>). If QlikView cannot interpret a field value as a valid image reference, the value itself will be displayed.

Click  to open the **Image Settings** popup.

- **Image Settings Popup:**
  - **No Stretch:** Displays the image without stretching. This may cause parts of the picture to be invisible or only part of the object to be filled.
  - **Fill:** The image is stretched to fit the object area without keeping the aspect ratio of the image.
  - **Keep Aspect:** The image is stretched as far as possible to fill the object area while keeping the aspect ratio.
  - **Fill with Aspect:** The image is stretched to fill the object area in both directions while keeping the aspect ratio.
  - **Hide Text When Image is Missing:** No text will be displayed if QlikView cannot interpret the image reference.
- **Info as Image:** When selecting this option, QlikView will display image info linked to the field value through info load/select in the script. If no image is available for the field value, the value itself will be displayed, unless the **Hide Text When Image Missing** box is checked.

### List Box properties

This section describes **List Box** properties.

#### Text Align

Here you set the alignment of text field values in the list box.

#### Number Align

Here you set the alignment of numeric field values in the list box.

#### Auto Columns

The number of columns is automatically selected.

#### Fixed Number of Columns

If multiple columns are allowed, specify the number of columns in the input field, or drag the slider to the desired number.

#### Background Color

Sets the background to a color, either a solid color or a gradient. Click  to choose the color.

#### Background Image

Sets an image as background. Click  to browse for an image. Click  to open the **Image** popup.

- **Image Popup:**
  - **No Stretch:** Displays the image without stretching. This may cause parts of the picture to be invisible or only part of the object to be filled.
  - **Fill:** The image is stretched to fit the object area without keeping the aspect ratio of the image.
  - **Keep Aspect:** The image is stretched as far as possible to fill the object area while keeping the aspect ratio.
  - **Fill with Aspect:** The image is stretched to fill the object area in both directions while keeping the aspect ratio.
  - **Horizontal:** **Left**, **Centered** or **Right** alignment.
  - **Vertical:** **Top**, **Centered** or **Bottom** alignment.
  - **Transparency:** Set the level of transparency by entering a value or by dragging the slider. At 100% the background will be completely transparent.

More.../Less...

- **General:**
  - **Show as TreeView:** Shows the list box as a tree view. This control is only relevant if the field contains the path representation of nodes in a hierarchy. Such a field can be generated using the **Path** parameter of the **Hierarchy** prefix.
  - **With Separator:** Sets the character that should be interpreted as separator in the path used for the **Tree View**.
  - **Search Mode:**
    - **Default Search Mode:**  
Here you may determine the default search mode, **Wildcard**, **Fuzzy**, **Normal** and **Associative**, to be used in any text search.

*Associative is available as a search mode for list boxes only.*

- **Include Excluded Values in Search:** The drop-down list lets you choose between **Yes**, **No** or **<use default>** which applies the default setting as specified under **User Preferences, General**.
- **Suppress Horizontal Scrollbar:** Check this option to suppress the horizontal scrollbar that is normally displayed when field values are too wide to fit the specified width of the list box. Instead, field values will be truncated as needed.
- **Order by Column:** In sheet objects with more than one column, values are displayed row-wise in the sort order specified. The **Order by Column** option switches to column-wise display.
- **Cell Borders:** The field values will be separated by horizontal lines, resembling the rows of a table. **Cell borders** are automatically activated when the **Wrap Cell Text** option is checked, but may be subsequently deactivated.
- **Wrap Cell Text:** With this option selected, a cell will display its contents in more than one row.
- **Cell Rows:** Set the number of cell rows.

- **Print All Values:** The normal print behavior for list boxes is to print only possible values. By marking this check box, all values (also excluded values) will be printed.
- **Layout-Dependent Print:** By marking this check box, the list box will be printed as it appears on the screen in terms of multiple columns, selection color coding of cells etc. This may be useful e.g. when including list boxes in reports.
- **Null Symbol:** The symbol entered here will be used for displaying null values in the object.
- **Missing Symbol:** The symbol entered here will be used for displaying missing values in the object.
- **Style:**
  - **Text:** To set the font type click .
  - **Caption Font:** To set the caption font click .
  - **Active Caption:** To set the background color for the active caption click . To set the text color click .
  - **Inactive Caption:** To set the background color for the inactive caption click . To set the text color click .
  - **Use Border:** Mark this check box in order to use a border around the sheet object. Click  to set the color of the border.
  - **Border Width:** Specify the width of the border in the input field, or drag the slider to the desired width. The width is specified in pixels.
  - **Rounded Corners:** Click  to open the **Rounded Corners** popup.

*Rounded Corners is only available if you have selected Advanced Styling Mode in Document Properties: General.*

- **Rounded Corners Popup:**
  - Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected.
  - Set the **Squareness** value by entering a value.
- **Scrollbar Width:** Specify the width of the border in the input field, or drag the slider to the desired width. The width is specified in pixels. This control affects both the width and the relative size of the scroll bar symbols.

## List Box Properties: Caption

This section describes Caption properties.

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.

The value may be entered as a calculated formula.

Click *fx* to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

### More.../Less...

**More.../Less...** contains **Icons in Caption**. This section describes several elements in **Icons Caption**.

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!
- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Maximize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click *fx* to open

the **Edit Expression** dialog.

It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.

- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.

Click  to open the popup.

- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## List Box Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.
- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.

- **Share with:** Choose either **Share with everyone** or **Share by username**.
- **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.13 Statistics Box - AJAX/Webview

Statistics boxes can show most types of statistical entities such as sum, average, minimum etc. of the possible values of a field. The calculations are made dynamically, i.e. the display changes instantaneously as selections are made in sheet objects.

### Statistics Box: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

Object Menu properties

| Property           | Description                                                                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Properties...      | Opens the <b>Properties</b> dialog for the active sheet object.                                                                                                                                                                     |
| Notes              | Allows creating and sharing notes about the current object.                                                                                                                                                                         |
| Select Possible    | All non-excluded values in the sheet object are selected.                                                                                                                                                                           |
| Select Excluded    | All excluded values in the sheet object are selected.                                                                                                                                                                               |
| Select All         | All values in the sheet object are selected.                                                                                                                                                                                        |
| Clear              | Clears all the current selections in the active sheet object. Clicking on the  icon in the object caption (if shown) produces the same result. |
| Clear Other Fields | Clears the selections in all the other sheet objects, while maintaining the ones in the currently active sheet object.                                                                                                              |
| Lock               | Locks the selected value(s) in the active sheet object. (Unavailable if no selections have been made).                                                                                                                              |
| Unlock             | Unlocks the locked value(s) in the active sheet object. (Appears instead of <b>Lock</b> if selections have been locked).                                                                                                            |
| Copy               | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                  |

| Property                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Copy cell value to clipboard | Copies the selected cell value to the clipboard.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Print...                     | Opens the selected sheet object(s) in tabular format in another browser window.<br><br>Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                           |
| Send to Excel                | Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Clicking on the  icon in the object caption (if shown) produces the same result. |
| Export...                    | Opens the <b>Save as</b> dialog where path, file name and (table) file type for the exported data content can be specified.                                                                                                                                                                                                                                                                                                                                        |
| Delete                       | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Statistics Box Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

### Field

Select the field you want to show statistics for in the drop-down.

### Displayed Functions

In the list below, check the box to use the function. Enter an alternative label in the field to the right.

#### Numeric Count

Sample size, i.e. the number of numeric values among the possible values.

#### Null Count

Number of empty field values among the possible values.

#### Text Count

Number of alphanumeric values among the possible values.

#### Total Count

Total number of possible values. This is the same number as the frequency that can be shown in a list box.

#### Missing Count

Number of non-numeric values among the possible values.

#### Sum

Sample sum.

### Average

Sample arithmetic mean.

### Standard Deviation

Sample standard deviation.

### Skewness

Sample skewness.

### Kurtosis

Sample kurtosis.

### Min

Sample minimum.

### Max

Sample maximum.

### Only Value

Only possible numeric value.

## Statistics Box Properties: Presentation

The section describes **Statistics Box** properties.

### Show Standard Error

Displays the standard error of the average and the standard deviation.

### Cell Borders

Displays borders between the cells in the sheet object.

### Background Color

Sets the background to a color, either a solid color or a gradient. Click  to choose the color.

### Background Image

Sets an image as background. Click  to browse for an image. Click  to open the **Image** popup.

### Image Popup

**No Stretch:** Displays the image without stretching. This may cause parts of the picture to be invisible or only part of the object to be filled. **Fill:** The image is stretched to fit the object area without keeping the aspect ratio of the image. **Keep Aspect:** The image is stretched as far as possible to fill the object area while keeping the aspect ratio. **Fill with Aspect:** The image is stretched to fill the object area in both

directions while keeping the aspect ratio. **Horizontal:** **Left**, **Centered** or **Right** alignment. **Vertical:** **Top**, **Centered** or **Bottom** alignment. **Transparency:** Set the level of transparency by entering a value or by dragging the slider. At 100% the background will be completely transparent.

## More.../Less...

This section describes **More.../Less...** properties.

### Style

- **Text:** To set the font type click .
- **Caption Font:** To set the caption font type click .
- **Active Caption:** To set the background color for the active caption click . To set the text color click .
- **Inactive Caption:** To set the background color for the inactive caption click . To set the text color click .
- **Use Border:** Mark this check box in order to use a border around the sheet object. Click  to set the color of the border.
- **Border Width:** Specify the width of the border in the input field, or drag the slider to the desired width. The width is specified in pixels.
- **Rounded Corners:** Click  to open the **Rounded Corners** popup.

***Rounded Corners** is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.*

- Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected. Also select **Squareness** by entering a value.
- **Scroll Bar Width:** Specify the width of the border in the input field, or drag the slider to the desired width. The width is specified in pixels. This control affects both the width and the relative size of the scroll bar symbols.

## Statistics Box Properties: Caption

This section describes **Statistics Box** properties.

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.

The value may be entered as a calculated formula.

Click  to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

### More.../Less...

This section describes **More.../Less...** properties.

#### Icons in Caption

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!
- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Maximize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.

- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.  
Click  to open the popup.
- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Statistics Box Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.
- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.14 Multi Box - AJAX/WebView

The multi box is a sheet object that shows several fields simultaneously.

For each field in the multi box, you will also find a selection indicator: a small beacon that will give you information on the content of the multi box. A green selection indicator shows that there are selected values, a white that there are optional values, and a gray that there are no possible values in the drop-down list.

### Multi Box: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

Multi Box: Object Menu commands

| Command                      | Details                                                                                                                                                                                                                             |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Properties...                | Opens the <b>Properties</b> dialog for the active sheet object.                                                                                                                                                                     |
| Notes                        | Allows creating and sharing notes about the current object.                                                                                                                                                                         |
| Clear All Selections         | Clears all the current selections in the active sheet object. Clicking on the  icon in the object caption (if shown) produces the same result. |
| Lock All Selections          | Locks the selected value(s) in the active sheet object. (Unavailable if no selections have been made).                                                                                                                              |
| Unlock All Selections        | Unlocks the locked value(s) in the active sheet object. (Appears instead of <b>Lock</b> if selections have been locked).                                                                                                            |
| Copy                         | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                  |
| Copy cell value to clipboard | Copies the selected cell value to the clipboard.                                                                                                                                                                                    |
| Delete                       | Removes the selected object from the sheet.                                                                                                                                                                                         |

### Multi Box Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

## Field

To add an item click . Select a field in the drop-down. The  icon moves the items in the list. The  icon removes items from the list. The object will contain the values of the selected field.

For more information click the **More...** button.

## Label

Enter the label name. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.

## Representation

This section describes options in **Representation**.

### Text

When selecting this option, the field values will always be interpreted and displayed as text.

### Image

When selecting this option QlikView will try to interpret each field value as a reference to an image. The reference may be a path to an image file on disk (e.g. *C:\Mypic.png*) or inside the QlikView document (e.g. *qmem://<Name>/<Peter>*). If QlikView cannot interpret a field value as a valid image reference, the value itself will be displayed. Click  to open the **Image Settings** popup.

- **Image Settings Popup:**
  - **Image Stretch:**
    - **No Stretch:** Displays the image without stretching. This may cause parts of the picture to be invisible or only part of the object to be filled.
    - **Fill:** The image is stretched to fit the object area without keeping the aspect ratio of the image.
    - **Keep Aspect:** The image is stretched as far as possible to fill the object area while keeping the aspect ratio.
    - **Fill with Aspect:** The image is stretched to fill the object area in both directions while keeping the aspect ratio.
    - **Hide Text When Image is Missing:** No text will be displayed if QlikView cannot interpret the image reference.
    - **Info as Image:** When selecting this option QlikView will display image info linked to the field value via info load/select in the script. If no image is available for the field value, the value itself will be displayed, unless the **Hide Text When Image Missing** box is checked.

## Search Mode

Here you may determine the default search mode, **Wildcard**, **Fuzzy**, **Normal** and **Associative**, to be used in any text search.

*Associative is available as a search mode for list boxes only.*

## Include Excluded Values in Search

The drop-down list lets you choose between **Yes**, **No** or **<use default>** which applies the default setting as specified under **User Preferences, General**.

## Dropdown Select Settings

Click  to open the popup.

- **Dropdown Select Settings Popup:**

- **Ignore Null:** NULL-values are not considered for the sake of displaying possible values of a specific field.
- **Hide Excluded:** Toggles whether the excluded values of the field should be shown or not. Excluded values become unselectable as well.
- **Show Frequency:** Toggles the status for whether the frequency of a field value is shown or not. By frequency is meant the number of selectable combinations in which the value occurs. This option is not available for calculated fields.

### In Percent

Toggles the status for whether the frequency should be shown in absolute numbers or as percentages of the total number of entries.

- **Override Locked Field:** Checking this option enables selections to be made in the sheet object even if it is locked. The sheet object will still be locked for selections made elsewhere in the document.
- **Read Only:** Checking this option will prevent making selections in the sheet object. However, it will still reflect selections made elsewhere in the document.

- **Dropdown Select Alignment:** Click  to open the popup.

- **Dropdown Select Alignment Popup:**

- **Number Align:** Here you set the alignment of numeric field values in the list box.
    - **Text Align:** Here you set the alignment of text field values in the list box.
    - **Rows and Columns:** Click  to open the popup.

- **Rows and Columns Popup:** This section outlines the Rows and Columns Popup elements.

- **Single Column:** With this option checked, the list box field values will always be presented in a single column.
        - **Show Horizontal Scrollbar:** Check this box to display the horizontal scroll bar.
        - **Multiple Columns:** With this option checked, the list box field values will be presented in a two or more columns.

- **Multiline Cells:** If this option is checked, the text will be displayed in two or more rows.
  - Specify the number of rows to display in the input box, or drag the slider to the desired number.
- **Order by Column:** In sheet objects with more than one column, values are displayed row-wise in the sort order specified. The **Order by Column** option switches to column-wise display.
- **Cell Border:** The field values will be separated by horizontal lines, resembling the rows of a table. Cell Border is automatically activated when the **Wrap Text** option is checked, but may be consequentiality deactivated.

## Sort

Sets the sort order of the values in the sheet object. Some sort options may not be available for all sheet objects.

If more than one sort order is specified, the sort order will be state, expression, frequency, numeric, text, load order. **State** refers to the logical state (selected, optional, or excluded).

### Primary Sort

**Y-Value:** Sets whether the dimension values should be sorted according to the numeric value of the y-axis. This option is not available for calculated dimensions. **Frequency:** Sorts the field values by frequency (number of concurrences in the table). **Numeric Value:** Sorts the field values by their numeric values. **Text:** Sorts the field values in alphabetical order. **Load Order:** Sorts the field values by the initial load order.

### Secondary Sort

**Frequency:** Sorts the field values by frequency (number of concurrences in the table).

**Numeric Value:** Sorts the field values by their numeric values.

**Text:** Sorts the field values in alphabetical order.

**Load Order:** Sorts the field values by the initial load order.

### Sort by Expression

Sorts the field values according to the expression entered. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

### Keep Selected on Top

Enable this to keep the selected values on top.

### Number Format

Each field has a default number format which can be set in the Document Properties: Number page. It is however possible to use a separate number format for an individual sheet object.

This property page applies to the active object and contains the following controls for formatting values:

- **Override Default Settings:** Select to override the default settings for the active object.
- **Number Format:** Choose a number format from the alternatives below.

- **Mixed**: Both numbers and text. Numbers are shown in original format.
- **Number**: Shows numeric values with the number of digits set in the **Precision** field.
- **Integer**: Shows numeric values as integers.
- **Fixed to**: Shows numeric values as decimal values with the number of decimal digits set in the **Decimals** field.
- **Money**: Shows values in the format set in the **Format Pattern** field.
  - The default format is the Windows Currency setting.
- **Date**: Shows values that can be interpreted as dates in the format set in the **Format Pattern** field.
- **Time**: Shows values that can be interpreted as time in the format set in the **Format Pattern** field.
- **Timestamp**: Shows values that can be interpreted as date + time in the format set in the **Format Pattern** field.
- **Interval**: Shows time as sequential time increments (e.g. format = mm shows the value as the number of minutes since calendar start (1899:12:30:24:00)).
- **Format Pattern**: The format code that further specifies the display format of the field.
- **ISO**: Sets the format to the ISO standard.

*Only valid for **Date**, **Time**, **Timestamp** and **Interval**.*

- **Sys**: Sets the format to the system settings.
- **Precision**: The number of digits that will be displayed.
- **Decimals**: Sets the number of decimals included.
- **Decimals Separator**: Sets the symbol for decimal separators.
- **Thousand Separator**: Sets the symbol for thousand separators.
- **In Percent**: Shows formatting in percentage instead of absolute numbers. The setting is only available for **Number**, **Integer** and **Fixed to**.
- **Preview**: Shows a preview of the number format specified above.

## Multi Box Properties: Presentation

### Style

Choose between the styles **Borders** and **Light**.

### Text Align

Here you set the alignment of text field values in the list box.

### Number Align

Here you set the alignment of numeric field values in the list box.

### Sort by Applicability

Sorts the fields in the multi box according to whether they contain possible field values or not. Fields lacking possible field values are dynamically moved down if this check box is marked.

## Grid Style

Mark the check box if you want the grid style appearance for the multi box.

*This option is not applicable in AJAX/WebView.*

## Limit Drop-down to

By marking this check box you can limit the length of opened drop-down list boxes in the multi box. Enter the maximum number of values to be shown in the edit box, or use the slider to set the desired value.

## Background Color

Sets the background to a color, either a solid color or a gradient. Click  to choose the color.

## Background Image

Sets an image as background. Click  to browse for an image. Click  to open the **Image** popup.

## Image Popup

- **No Stretch:** Displays the image without stretching. This may cause parts of the picture to be invisible or only part of the object to be filled.
- **Fill:** The image is stretched to fit the object area without keeping the aspect ratio of the image.
- **Keep Aspect:** The image is stretched as far as possible to fill the object area while keeping the aspect ratio.
- **Fill with Aspect:** The image is stretched to fill the object area in both directions while keeping the aspect ratio.
- **Horizontal:** **Left**, **Centered** or **Right** alignment.
- **Vertical:** **Top**, **Centered** or **Bottom** alignment.
- **Transparency:** Set the level of transparency by entering a value or by dragging the slider. At 100% the background will be completely transparent.

## More.../Less...

This section describes **Style** options in **More.../Less...**

### Text

To set the font type click  .

### Caption Font

To set the caption font type click  .

### Active Caption

To set the background color for the active caption click  . To set the text color click  .

## Inactive Caption

To set the background color for the inactive caption click . To set the text color click .

## Use Border

Mark this check box in order to use a border around the sheet object. Click  to set the color of the border.

## Border Width

Specify the width of the border in the input field, or drag the slider to the desired width. The width is specified in pixels.

## Rounded Corners

Click  to open the **Rounded Corners** popup.

***Rounded Corners** is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.*

- **Rounded Corners Popup:** Select Fixed or Relative roundness
  - Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected. Select **Squareness** by entering a value.
- **Scroll Bar Width:** Specify the width of the border in the input field, or drag the slider to the desired width. The width is specified in pixels. This control affects both the width and the relative size of the scroll bar symbols.

## Multi Box Properties: Caption

### Caption

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.

The value may be entered as a calculated formula.

Click  to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.

- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

### More.../Less...

This section describes **Icon in Caption** and its properties. **Icon in Caption** exists inside **More.../Less...**

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!
- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Maximize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.
- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.  
Click  to open the popup.
- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Multi Box Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.
- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.15 Table Box - AJAX/WebView

The table box is a sheet object that shows several fields simultaneously. The content of every row is logically connected. The columns may be fetched from different internal tables, letting the user create tables from any possible combination of fields.

By right-clicking the object, the **Object Menu** will be displayed.

## The Table Box: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

Object Menu properties

| Property                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Properties...                | Opens the <b>Properties</b> dialog for the active sheet object.                                                                                                                                                                                                                                                                                                                                                                                                      |
| Notes                        | Allows creating and sharing notes about the current object.                                                                                                                                                                                                                                                                                                                                                                                                          |
| Clear All Selections         | Clears all the current selections in the active sheet object. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                    |
| Copy                         | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                                                                                                   |
| Copy cell value to clipboard | Copies the selected cell value to the clipboard.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Print...                     | <p>Opens the selected sheet object(s) in tabular format in another browser window.</p> <p>Clicking on the  icon in the object caption (if shown) produces the same result.</p> <p>Images in a table box will not be printed using the Ajax client.</p>                                                                                                                            |
| Send to Excel                | Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Clicking on the  icon in the object caption (if shown) produces the same result. |
| Export...                    | <p>Opens the <b>Save as</b> dialog where path, file name and (table) file type for the exported data content can be specified.</p> <div style="border: 1px solid gray; padding: 5px; margin-top: 10px;">  <i>Export to Excel can fail when using large data sets in AJAX mode due to product limitations.</i> </div>                                                              |
| Minimize                     | Iconizes the object. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if minimizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                                                                                                |

| Property | Description                                                                                                                                                                                                                                                                                                                                                                             |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Restore  | Restores a minimized or maximized object to its previous size and location. Double-clicking the icon of a minimized object or clicking the  icon in the object caption (if shown) of a maximized object produces the same result. This command is available only for minimized or maximized objects. |
| Maximize | Enlarges the object to fill the sheet. Clicking on the <input type="checkbox"/> icon in the object caption (if shown) produces the same result. This command is available only if maximizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                                                            |
| Delete   | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                                                                             |

## Table Box Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

### Column Fields

Select a field in the drop-down.

To add an item click . Select a field in the drop-down. The  icon moves the items in the list. The  icon removes items from the list. The object will contain the values of the selected field.

For more information click the **More...** button.

### Field

- **Field:** The field that is currently edited.
- **Label:** Enter the label name. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
- **Label Align:** Set the alignment of the label in the table box.
- **Representation:** This section describes **Representation** options.
  - **Text:** When selecting this option, the field values will always be interpreted and displayed as text.
  - **Image:** When selecting this option QlikView will try to interpret each field value as a reference to an image. The reference may be a path to an image file on disk (e.g. C:\Mypic.png) or inside the QlikView document (e.g. qmem://<Name>/<Peter>). If QlikView cannot interpret a field value as a valid image reference, the value itself will be displayed.

Click  to open the **Image Settings** popup.

    - **Image Settings Popup:**
      - **No Stretch:** Displays the image without stretching. This may cause parts of the picture to be invisible or only part of the object to be filled.

- **Fill:** The image is stretched to fit the object area without keeping the aspect ratio of the image.
  - **Keep Aspect:** The image is stretched as far as possible to fill the object area while keeping the aspect ratio.
  - **Fill with Aspect:** The image is stretched to fill the object area in both directions while keeping the aspect ratio.
  - **Hide Text When Image is Missing:** No text will be displayed if QlikView cannot interpret the image reference.
  - **Info as Image:** When selecting this option, QlikView will display image info linked to the field value through info load/select in the script. If no image is available for the field value, the value itself will be displayed, unless the **Hide Text When Image Missing** box is checked.
  - **Number Align:** Set the alignment of numeric field values in the table box.
  - **Text Align:** Set the alignment of text field values in the table box.
  - **Ignore Null:** NULL-values are not considered for the sake of displaying possible values of a specific field.
  - **Dropdown Select:** If this check box is selected for a field column, a drop-down icon will appear to the left of the column header. By clicking the icon, a list box showing all field values of the field will be opened over the table. It is then possible to make selections and searches in the same manner as if the field had been a row in a multi box.
  - **Search Mode:**
    - **Default Search Mode:**  
Here you may determine the default search mode, **Wildcard**, **Fuzzy**, **Normal** and **Associative**, to be used in any text search.
-  *Associative is available as a search mode for list boxes only.*
- **Include Excluded Values in Search:** The drop-down list lets you choose between **Yes**, **No** or **<use default>** which applies the default setting as specified under **User Preferences, General**.

## Sort

Sets the sort order of the values in the sheet object. Some sort options may not be available for all sheet objects.

If more than one sort order is specified, the sort order will be state, expression, frequency, numeric, text, load order. **State** refers to the logical state (selected, optional, or excluded).

- **Primary Sort: Y-Value:** Sets whether the dimension values should be sorted according to the numeric value of the y-axis. This option is not available for calculated dimensions. **Frequency:** Sorts the field values by frequency (number of concurrences in the table). **Numeric Value:** Sorts the field values by their numeric values. **Text:** Sorts the field values in alphabetical order. **Load Order:** Sorts the field values by the initial load order.

- **Secondary Sort: Frequency:** Sorts the field values by frequency (number of concurrences in the table).  
**Numeric Value:** Sorts the field values by their numeric values.  
**Text:** Sorts the field values in alphabetical order.  
**Load Order:** Sorts the field values by the initial load order.
- **Sort by Expression:** Sorts the field values according to the expression entered. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

## Number Format

Each field has a default number format which can be set in the Document Properties: Number page. It is however possible to use a separate number format for an individual sheet object. This property page applies to the active object and contains the following controls for formatting values: Override Default Settings>Select to override the default settings for the active object.Number FormatChoose a number format from the alternatives below.

- **Mixed:** Both numbers and text. Numbers are shown in original format.
- **Number:** Shows the numeric values with the number of digits set in the **Precision** field.
- **Integer:** Shows numeric values as integers.
- **Fixed to:** Shows numeric values as decimal values with the number of decimal digits set in the **Decimals** field.
- **Money:** Shows values in the format set in the **Format Pattern** field. The default format is the Windows Currency setting.
- **Date:** Shows values that can be interpreted as dates in the format set in the **Format Pattern** field.
- **Time:** Shows values that can be interpreted as time in the format set in the **Format Pattern** field.
- **Timestamp:** Shows values that can be interpreted as date + time in the format set in the **Format Pattern** field.
- **Interval:** Shows time as sequential time increments (e.g. format = mm shows the value as the number of minutes since calendar start (1899:12:30:24:00).Format PatternThe format code that further specifies the display format of the field.
- **ISO:** Sets the format to the ISO standard. Only valid for **Date**, **Time**, **Timestamp**, and **Interval**.
- **Sys:** Sets the format to the system settings.
- **Precision:** The number of digits that will be displayed.
- **Decimals:** Sets the number of decimals included.
- **Decimals Separator:** Sets the symbol for decimal separators.
- **Thousand Separator:** Sets the symbol for thousand separators.
- **In Percent:** Shows formatting in percentage instead of absolute numbers. This setting is only available for **Number**, **Integer**, and **Fixed to**.
- **Preview:** Shows a preview of the number format specified above.

## Table Box Properties: Presentation

This section describes **Table Box** properties.

## Suppress Header Row

Displays the table without header (label) row.

## Sort Indicators

Displays a sort indicator icon (arrow) in the header of the column. The direction of the icon indicates whether the column is sorted ascending or descending.

## Selection Indicators

Displays selection indicators (beacons) in the table columns containing fields with selections.

## Allow Move Column

Deselect this check box to disable moving columns.

## Background Color

Sets the background to a color, either a solid color or a gradient. Click  to choose the color.

## Background Image

Sets an image as background. Click  to browse for an image. Click  to open the **Image** popup.

## Image Popup

- **No Stretch:** Displays the image without stretching. This may cause parts of the picture to be invisible or only part of the object to be filled.
- **Fill:** The image is stretched to fit the object area without keeping the aspect ratio of the image.
- **Keep Aspect:** The image is stretched as far as possible to fill the object area while keeping the aspect ratio.
- **Fill with Aspect:** The image is stretched to fill the object area in both directions while keeping the aspect ratio.
- **Horizontal:** **Left**, **Centered** or **Right** alignment.
- **Vertical:** **Top**, **Centered** or **Bottom** alignment.
- **Transparency:** Set the level of transparency by entering a value or by dragging the slider. At 100% the background will be completely transparent.

## More.../Less...

This section describes **More.../Less...** properties.

### General

- **Style:** Choose an appropriate style from the drop-down list.
- **Stripes every \_ Rows:** Specify if and how long intervals in rows, shaded stripes should appear.
- **Vertical Labels:** Displays the column titles vertically.
- **Wrap Header:** The contents of the header will be wrapped in two or more lines.
- **Wrap Cell Text:** The contents of the data cells will be wrapped in two or more lines.

## Style

- **Font:** To set the font type click .
- **Active Caption:** To set the background color for the active caption click . To set the text color click .
- **Inactive Caption:** To set the background color for the inactive caption click . To set the text color click .
- **Scroll Bar Background:** To set the scroll bar background color click .
- **Scroll Bar Slider:** To set the scroll bar slider color click .
- **Scroll Bar Width:** Specify the width of the border in the input field, or drag the slider to the desired width. The width is specified in pixels. This control affects both the width and the relative size of the scroll bar symbols.
- **Use Border:** Mark this check box in order to use a border around the sheet object. Click  to set the color of the border.
- **Border Width:** Specify the width of the border in the input field, or drag the slider to the desired width. The width is specified in pixels.
- **Rounded Corners:** Click  to open the **Rounded Corners** popup.

***Rounded Corners** is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.*

- **Rounded Corners Popup:** Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected. Select **Squareness** by entering a value.

## Table Box Properties: Caption

### Caption

This section describes **Caption** properties.

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.

The value may be entered as a calculated formula.

Click  to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.

- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

## More.../Less...

This section describes **More.../Less...** properties.

### Icons in Caption

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!
- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Maximize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.
- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.  
Click  to open the popup.

- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Table Box Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.
- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.16 Input Box - AJAX/Webview

The input box is a sheet object that is used to enter data into QlikView variables and to show their values.

By right-clicking the object, the **Object Menu** will be displayed.

### Input Box: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

Input Box: Object Menu commands

| Command       | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Properties... | Opens the <b>Properties</b> dialog for the active sheet object.                                                                                                                                                                                                                                                                                                                                                                                                      |
| Notes         | Allows creating and sharing notes about the current object.                                                                                                                                                                                                                                                                                                                                                                                                          |
| Copy          | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                                                                                                   |
| Minimize      | Iconizes the object. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if minimizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                                                                                                |
| Restore       | Restores a minimized or maximized object to its previous size and location. Double-clicking the icon of a minimized object or clicking the  icon in the object caption (if shown) of a maximized object produces the same result. This command is available only for minimized or maximized objects.                                                                            |
| Maximize      | Restores a minimized or maximized object to its previous size and location. Double-clicking the icon of a minimized object or clicking the  icon in the object caption (if shown) of a maximized object produces the same result. This command is available only for minimized or maximized objects.                                                                            |
| Print...      | Opens the selected sheet object(s) in tabular format in another browser window.<br><br>Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                           |
| Send to Excel | Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Clicking on the  icon in the object caption (if shown) produces the same result. |

| Command   | Details                                                                                                                     |
|-----------|-----------------------------------------------------------------------------------------------------------------------------|
| Export... | Opens the <b>Save as</b> dialog where path, file name and (table) file type for the exported data content can be specified. |
| Delete    | Removes the selected object from the sheet.                                                                                 |

## Input Box Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

To add an item click . Select a variable in the drop-down. The  icon moves the items in the list. The  icon removes the items from the list. The object will contain the values of the selected variable.

For more information click the **More...** button.

The **Variables** property in **Input Box** has the following Fields:

- **Variable:** The available variables are listed in the drop-down.
- **Label:** An alternative name for the displayed variable can be entered here. It will be used as variable title in the input box. The label may be defined as a calculated formula for dynamic update. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Align:** Select **Left**, **Centered** or **Right** alignment of the variable.
- **Row Color:** Set row color by clicking , and text color by clicking .

## Input Box Properties: Presentation

This section describes several properties in **Presentation**.

### Show Equal Sign

Displays an equal sign in the input box. The setting is general for all variables.

### Background Color

Sets the background to a color, either a solid color or a gradient. Click  to choose the color.

### Background Image

Sets an image as background. Click  to browse for an image. Click  to open the **Image** popup.

### Image Popup

- **No Stretch:** Displays the image without stretching. This may cause parts of the picture to be invisible or only part of the object to be filled.
- **Fill:** The image is stretched to fit the object area without keeping the aspect ratio of the image.

- **Keep Aspect:** The image is stretched as far as possible to fill the object area while keeping the aspect ratio.
- **Fill with Aspect:** The image is stretched to fill the object area in both directions while keeping the aspect ratio.
- **Horizontal:** **Left**, **Centered** or **Right** alignment.
- **Vertical:** **Top**, **Centered** or **Bottom** alignment.
- **Transparency:** Set the level of transparency by entering a value or by dragging the slider. At 100% the background will be completely transparent.

## More.../Less...

This section describes the **Style** settings in **More.../Less...**

### Text

To set the font type click .

### Caption Font

To set the caption font type click .

### Active Caption

To set the background color for the active caption click . To set the text color click .

### Inactive Caption

To set the background color for the inactive caption click . To set the text color click .

### Use Border

Mark this check box in order to use a border around the sheet object. Click  to set the color of the border.

### Border Width

Specify the width of the border in the input field, or drag the slider to the desired width. The width is specified in pixels.

### Rounded Corners

Click  to open the **Rounded Corners** popup.

*Rounded Corners is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.*

**Rounded Corners Popup:**

- Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected. Also select **Squareness** by entering a value.
- **Scroll Bar Width:** Specify the width of the border in the input field, or drag the slider to the desired width. The width is specified in pixels. This control affects both the width and the relative size of the scroll bar symbols.

## Input Box Properties: Caption

This section describes **Caption** properties.

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.  
The value may be entered as a calculated formula.

Click *fx* to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

## More.../Less...

This section describes the **More.../Less...** property, which contains several **Icon Caption** properties.

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!
- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.

- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Minimize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.
- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.  
Click  to open the popup.
- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Input Box Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.
- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object

will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.

- **Normal**: Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized**: Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...**: The following options are available:
  - **Owner**: Domain and User Id of the owner.
  - **Share Object**: Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with**: Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID)**: If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.17 Current Selections Box - AJAX/WebView

The current selections box is a sheet object that shows selections in the fields and their logical status. The current selections box shows the same data as the free floating Current Selections Window but can be positioned on the sheet as any other sheet object.

By right-clicking the object, the **Object Menu** will be displayed.

### Current Selections Box: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

Current Selections Box: Object Menu commands

| Command              | Details                                                                                                                                                                                                                             |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Properties...        | Opens the <b>Properties</b> dialog for the active sheet object.                                                                                                                                                                     |
| Notes                | Allows creating and sharing notes about the current object.                                                                                                                                                                         |
| Clear All Selections | Clears all the current selections in the active sheet object. Clicking on the  icon in the object caption (if shown) produces the same result. |
| Lock All Selections  | Locks the selected value(s) in the active sheet object. (Unavailable if no selections have been made).                                                                                                                              |

| Command                      | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Unlock all Selections        | Unlocks the locked value(s) in the active sheet object. (Appears instead of <b>Lock</b> if selections have been locked).                                                                                                                                                                                                                                                                                                                                             |
| Copy                         | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                                                                                                   |
| Copy cell value to clipboard | Copies the selected cell value to the clipboard.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Minimize                     | Iconizes the object. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if minimizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                                                                                                  |
| Restore                      | Restores a minimized or maximized object to its previous size and location. Double-clicking the icon of a minimized object or clicking the  icon in the object caption (if shown) of a maximized object produces the same result. This command is available only for minimized or maximized objects.                                                                               |
| Maximize                     | Enlarges the object to fill the sheet. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if maximizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                                                                               |
| Print...                     | Opens the selected sheet object(s) in tabular format in another browser window.<br><br>Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                           |
| Send to Excel                | Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Clicking on the  icon in the object caption (if shown) produces the same result. |
| Export...                    | Opens the <b>Save as</b> dialog where path, file name and (table) file type for the exported data content can be specified.                                                                                                                                                                                                                                                                                                                                          |
| Delete                       | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Current Selections Box Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

## Show Values

Displays a **Values** column showing the values selected in the fields.

### Show Status

Displays a **Status** column with colored beacons indicating the current logical status of the selections in the fields.

### Show Clear Icons

Each field row will display a small clear icon. Clicking the clear icon will clear selections in the field. No clear icon will be displayed for locked fields.

### Show Lock/Unlock Icons

Each field row will display a small lock or unlock icon. Clicking the icon will lock or unlock selections in the fields.

## Current Selection Box Properties: Presentation

This section describes Presentation properties.

### Use Column Labels

Displays a header row. Labels can be edited in the group below.

### Fields

Specify a label to be displayed in the header row above the **Fields** column.

### Values

Specify a label to be displayed in the header row above the **Values** column.

### Background Color

Sets the background to a color, either a solid color or a gradient. Click  to choose the color.

### Background Image

Sets an image as background. Click  to browse for an image. Click  to open the **Image** popup.

### Image Popup

- **No Stretch:** Displays the image without stretching. This may cause parts of the picture to be invisible or only part of the object to be filled.
- **Fill:** The image is stretched to fit the object area without keeping the aspect ratio of the image.
- **Keep Aspect:** The image is stretched as far as possible to fill the object area while keeping the aspect ratio.
- **Fill with Aspect:** The image is stretched to fill the object area in both directions while keeping the aspect ratio.
- **Horizontal:** **Left**, **Centered** or **Right** alignment.
- **Vertical:** **Top**, **Centered** or **Bottom** alignment.

- **Transparency:** Set the level of transparency by entering a value or by dragging the slider. At 100% the background will be completely transparent.

### More.../Less...

**More.../Less...** provides the following options for **Styles**:

- **Text:** To set the text color click . To set the font type click .
- **Label:** To set the background color for the label click . To set the text color click .
- **Caption Font:** To set the caption font type click .
- **Active Caption:** To set the background color for the active caption click . To set the text color click .
- **Inactive Caption:** To set the background color for the inactive caption click . To set the text color click .
- **Use Border:** Mark this check box in order to use a border around the sheet object. Click  to set the color of the border.
- **Border Width:** Specify the width of the border in the input field, or drag the slider to the desired width. The width is specified in pixels.
- **Rounded Corners:** Click  to open the **Rounded Corners** popup.

***Rounded Corners** is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.*

- **Rounded Corners Popup:**
  - Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected.
  - Select **Squareness** by entering a value.
- **Scroll Bar Width:** Specify the width of the border in the input field, or drag the slider to the desired width. The width is specified in pixels. This control affects both the width and the relative size of the scroll bar symbols.

## Current Selection Box Properties: Caption

This section describes Caption properties.

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.  
The value may be entered as a calculated formula.

Click  to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

## Icon Caption

Icon Caption consists of one property, **More.../Less...**, which contains several options that will be described in this section.

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!
- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Maximize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.

- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects. Click  to open the popup.
- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Current Selection Box Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.
- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.18 Button - AJAX/WebView

Buttons can be used in QlikView to perform commands or actions, e.g. export data to files, launch other applications or execute macros.

By right-clicking the object, the **Object Menu** will be displayed.

### Button: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

Button: Object Menu commands

| Command       | Details                                                                                                            |
|---------------|--------------------------------------------------------------------------------------------------------------------|
| Properties... | Opens the <b>Properties</b> dialog for the active sheet object.                                                    |
| Notes         | Allows creating and sharing notes about the current object.                                                        |
| Copy          | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images. |
| Delete        | Removes the selected object from the sheet.                                                                        |

### Button Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

### Button Text

Enter the text the button should display. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.

### Actions

To add an action click . The **Action Settings** popup for the new action opens instantly. It is also possible to select an action in the drop-down and to click  to edit. The  icon moves the items in the list. The  icon removes the items from the list.

### Actions Settings Popup

- **Type:** Choose a **Type** in the drop-down list.
- **Subtype:** Choose a **Subtype** in the drop-down list. The subtypes available depend on the **Action Type** chosen.

### Action Types and Actions

- **Selection**
  - **Select in Field:** Selects the values and fields that are specified. In the **Search String** you can specify a search mask, e.g. (A|B) will select both A and B.
  - **Select Excluded:** Selects the excluded values in the specified field.
  - **Select Possible:** Selects the possible values in the specified field.
  - **Toggle Select:** Toggles between the current selection and the specified **Field** and **Search String**. In the **Search String** you can specify a search mask, e.g. (A|B) will select both A and B.
  - **Forward:** Goes one step forward in the list of selections.
  - **Back:** Goes back one step in the list of selections.
  - **Pareto Select:** Makes a pareto selection in the specified field based on an expression and percentage. This type of selection is used to select the top contributors to a measure, typically in line of a general 80/20 rule. For example, to find the top customers that contribute to 80% of the turnover, Customer should be used as field, sum(Turnover) should be used as expression and 80 should be used as percentage.
  - **Lock Field:** Locks the selections in the specified field.
  - **Lock All:** Locks all values in all fields.
  - **Unlock Field:** Unlocks the selections in the specified field.
  - **Unlock All:** Unlocks all values in all fields.
  - **Unlock and Clear All:** Unlocks all values and clears all selections in all fields.
  - **Clear Other Fields:** Clears all related fields except the one specified.
  - **Clear All:** Clears all selections except locked ones.
  - **Clear Field:** Clears a specific field.
- **Layout**
  - **Activate Object:** Activates the object specified by **Object ID**. This function does not work in Ajax client.
  - **Activate Sheet:** Activates the sheet specified by **Sheet ID**.
  - **Activate Next Sheet:** Opens the next sheet in the document.
  - **Activate Previous Sheet:** Opens the previous sheet in the document.
  - **Minimize Object:** Minimizes the object specified by **Object ID**.
  - **Maximize Object:** Maximizes the object specified by **Object ID**.
  - **Restore Object:** Restores the object specified by **Object ID**.
- **Bookmark**
  - **Apply Bookmark:** Applies a bookmark specified by **Bookmark ID**. If two bookmarks have the same ID, the document bookmark is applied. To apply the server bookmark specify

Server\bookmarkID.

- **Create Bookmark:** Creates a bookmark from the current selection. Specify **Bookmark ID** and **Bookmark Name**. Select **Hidden** to create a hidden bookmark.
- **Replace Bookmark:** Replaces the bookmark specified by **Bookmark ID** with the current selection.
- **Print**
  - **Print Object:** Prints the object specified by **Object ID**. Specify the **Printer name** if the object should be sent to another printer than the default printer. (Not available as document and sheet trigger.)
  - **Print Sheet:** Prints the sheet specified by **Sheet ID**. (Not available as document and sheet trigger.) This function does not work in AJAX client.
  - **Print Report:** Prints the report specified by **Report ID**. Specify the **Printer name** if the report should be sent to another printer than the default printer. Mark the check box **Show Print Dialog** if you want the Windows print dialog to be shown. (Not available as document and sheet trigger.)
- **External:** Some clients may not handle this setting!
- **Export:** Exports a table containing a specific set of fields, but only those records that are applicable according to the made selection are exported. Click on the **Setup** button on the **Actions** page to open the **Export Action Settings** dialog. This is not available as document or sheet trigger.

*This function does not work in AJAX client.*

- **Launch:** Launches an external program. The following settings can be configured in the **Actions** dialog:
  - **Application:** Click on **Browse...** to find the application that should be launched. (Not available as document and sheet trigger.)
  - **Filename:** Enter the path to the file that should be opened with the application specified above. (Not available as document and sheet trigger.)
  - **Parameters:** Specify parameters for the command line from which the application is started. (Not available as document and sheet trigger.)
  - **Working Directory:** Sets the working directory for the application to be launched. (Not available as document and sheet trigger.)
  - **Exit application when QlikView is closed:** Forces the application to be closed when QlikView is exited. (Not available as document and sheet trigger.)

*This function does not work in AJAX client.*

- **Open URL:** You can use **Open URL** to open a URL to a QlikView document from within another QlikView document (document chaining). This setting opens the URL in the default web browser. This function cannot be used as a document and sheet trigger. If using **Open URL**, make sure to enter the document name in the action-string in lower case. Where possible, use **Open QlikView Document** instead of **Open URL**.

*The use of Javascript in URLs is prevented by default. You can allow Javascript in URLs by changing the `PreventJavascriptInObjectActions` parameter in the `custom.config` file.*

- **Open QlikView Document:** You can use **Open QlikView Document** to open a QlikView document from within another QlikView document (document chaining). This function cannot be used as a document or sheet trigger. For more information, see *Document chaining examples (page 1654)*.
- **Run Macro:** Enter the path and name of the macro to be run. Type any name for which it is possible to later create a macro in the **Edit Module** dialog, or a **calculated expression** for dynamic update.
- **Set Variable:** Assigns a value to the specified variable.
- **Show Information:** Shows the associated information, such as a text file or an image for the field specified by **Field**. This function does not work in AJAX client.
- **Close This Document:** Closes the active QlikView document.
- **Reload:** Performs a reload on the current document. This function does not work both in AJAX client and IE-plugin.
- **Dynamic Update:** Performs a dynamic update of the data in the currently loaded document. The statement for the dynamic update is to be entered in the **Statement** field. The intended usage of Dynamic Update allows a QlikView Administrator to feed limited amounts of data in to a QlikView document from a single source without running a reload of the document. Analysis can then be performed by multiple clients connecting to the QlikView Server.

*The uploaded information is stored in RAM only so any data added or updated using Dynamic Update will be lost if a reload of the document is performed.*

The following grammar describes the possible statements and their components that can be used with the Dynamic Update feature:

- `statements ::= statement { "," statement }`
- `statement ::= insert_statement | update_statement | delete_statement | begin_transaction_statement | commit_transaction_statement`
- `insert_statement ::= "INSERT" "INTO" ("*" | table_name) field_list "VALUES" value_list { "," value_list } ["KEY" ["AUTO" | (" (" field_list ")") ] ["REPLACE" (["WITH" "ONE"] | "EACH") ]]`
- `update_statement ::= "UPDATE" ("*" | table_name) set_clause { "," | set_clause } "WHERE" condition ["AUTO" "INSERT"]`
- `delete_statement ::= "DELETE" "FROM" ("*" | table_name) "WHERE" condition`
- `begin_transaction_statement ::= "BEGIN" ("TRANSACTION" | "TRAN") [trans_name]`
- `commit_transaction_statement ::= "COMMIT" ["TRANSACTION" | "TRAN"] [trans_name]`
- `table_name ::= identifier | quoted_name`
- `field_list ::= "(" field_name { "," field_name } ")"`
- `value_list ::= "(" value { "," value } ")"`
- `set_clause ::= "SET" field_name "=" any_valid_non_aggregated_qlikview_expression`
- `field_name ::= identifier | quoted string`

- value ::= identifier | any\_qlikview\_number | quoted string
- condition ::= any\_valid\_non\_aggregated\_qlikview\_expression
- identifier ::= any\_qlikview\_identifier
- quoted\_string ::= "[" (^)]+ "]"

**Example:**

```
UPDATE AbcTable SET Discount = 123 WHERE AbcField=1
```

To use this feature, Dynamic Update must be allowed both on the Document and on the Server.

## Document chaining examples

You can use **Open QlikView Document** to create document chaining.

The following settings can be applied:

- **Transfer State:** to transfer the selections from the original document to the destination document. The destination document will first be cleared of selections.
- **Apply state on top of current:** to retain the destination document's selections and apply the original document's selections on top of them.

Using **Apply state on top of current** can return unexpected results if the selections made in the two documents are conflicting.

- **Open in same Window:** to open the new document in the same browser tab when using the AJAX ZFC client.

**Open QlikView Document** action is not supported for non domain users when using the QlikView plug-in.

QlikView documents: The extension of the destination file must be included. Relative paths to navigate from one QlikView document to another are supported in all clients, as long as the chained documents are stored in the same folder structure (mount).

The following examples show how to write the file path to the destination file:

**Example:** File located in the same folder structure (same mount).

- If the destination file is in the same folder:  
*DestinationDoc.qvw*
- If the destination file is in a sub folder:  
*SubFolder/DestinationDoc.qvw*
- If the destination file is in an upper folder:  
*../DestinationDoc.qvw*

- If the destination file is in an upper and parallel folder:

*../ParallelFolder/DestinationDoc.qvw*

**Example:** File located in a different folder structure (different mount). The relative path between different mounts is supported in the Ajax client only.

- If the destination file is in a different mount:

*../DifferentMount/DestinationDoc.qvw*

**Example:** Using the mount path to point to a QlikView document. Setting the path to mounted folders is supported in the Ajax client only.

- If the destination file is in the same mounted folder:

*Mount\DestinationDoc.qvw*

- If the destination file is in a different mounted folder:

*\DifferentMount\DestinationDoc.qvw*

*Document chaining with mounted folders does not work with the QlikView plug-in.*

**Example:** Using the absolute path to point to a QlikView document. The use of absolute paths for document chaining is supported in the Ajax client and in QlikView Desktop.

- Absolute path to the Local Root folder or mount:

*C:\...\DestinationDoc.qvw*

- Absolute path to a Network Share:

*\\SharedStorage\...\DestinationDoc.qvw*

QlikView apps in the Qlik Sense Cloud hub: you need the AppId, not the path. Apps need to be prepared and updated in QlikView Desktop. The AppId is found in the URL when the app is open in the hub.

### Example

If the URL is

*https://qcs.us.qlikcloud.com/qv/opendoc.htm?document=1cc71b323f172f93a8121ce1456cdg*. Then the AppId is *1cc71b323f172f93a8121ce1456cdg*.

### Enable Condition

Enter an expression that will determine the status of the button. If the expression returns 0, the button will be disabled, if the expression returns 1, the button will be enabled. If no expression is entered, 1 is assumed. Buttons that are disabled due to underlying status cannot be enabled by means of a condition.

The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

## Button Properties: Presentation

### Background Style

#### Aqua

Default for new buttons. Gives a rounded button with three dimensional glassy look. Click  to set a color.

#### Plain

Produces a traditional plain QlikView button. Click  to set a color.

#### System Default

Provides a solid background in the color defined for buttons in the operating system.

#### Single Image

Uses an image for the button. Click  to browse for an image.

#### Combined Image

Produces an image button with three parts, one for each possible state (active, inactive or depressed).

Click  to browse for an image. The image file must consist of three images of the button side by side, the first of the active button, the second of a depressed button and the third of a dimmed (inactive) button.

### Transparency

Sets the level of transparency of the object background by entering a value or by dragging the slider. At 100% the background will be completely transparent.

### Text Align

**Left**, **Centered** or **Right** alignment of the button text.

### More.../Less...

#### Styles

- **Text on Button:** To set the text color click . To set the font type click **Aa**.
- **Caption Font:** To set the caption font type click **Aa**.
- **Active Caption:** To set the background color for the active caption click . To set the text color click .
- **Inactive Caption:** To set the background color for the inactive caption click . To set the text color click .

- **Use Border:** Mark this check box in order to use a border around the sheet object. Click  to set the color of the border.
- **Border Width:** Specify the width of the border in the input field, or drag the slider to the desired width. The width is specified in pixels.
- **Rounded Corners:** Click  to open the **Rounded Corners** popup.

*Rounded Corners is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.*

Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected. Also select **Squareness** by entering a value.

## Button Properties: Caption

### Caption

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.  
The value may be entered as a calculated formula.

Click  to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

### More.../Less...

#### Icons in Caption

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!

- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!
- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Maximize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.
- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.  
Click  to open the popup.
- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Button Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info

icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.

- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.19 Text Object - AJAX/Webview

Text objects can be used for displaying text information or an image in the layout.

### Text Object: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

Object menu commands

| Command       | Description                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------|
| Properties... | Opens the <b>Properties</b> dialog for the active sheet object.                                                    |
| Notes         | Allows creating and sharing notes about the current object.                                                        |
| Copy          | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images. |
| Delete        | Removes the selected object from the sheet.                                                                        |

## Text Object Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

### Text

Enter the text the text object should display. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

### Actions

To add an action click . The **Action Settings** popup for the new action opens instantly. It is also possible to select an action in the drop-down and to click  to edit. The  icon moves the items in the list. The  icon removes the items from the list.

### Actions Settings Popup

The following options are available:

- **Type**: Choose a **Type** in the drop-down list.
- **Subtype**: Choose a **Subtype** in the drop-down list. The subtypes available depend on the **Action Type** chosen.

### Actions Types and Actions

Selection:

- **Select in Field**: Selects the values and fields that are specified. In the **Search String** you can specify a search mask, e.g. (A|B) will select both A and B.
- **Select Excluded**: Selects the excluded values in the specified field.
- **Select Possible**: Selects the possible values in the specified field.
- **Toggle Select**: Toggles between the current selection and the specified **Field** and **Search String**. In the **Search String** you can specify a search mask, e.g. (A|B) will select both A and B.
- **Forward**: Goes one step forward in the list of selections.
- **Back**: Goes back one step in the list of selections.
- **Pareto Select**: Makes a pareto selection in the specified field based on an expression and percentage. This type of selection is used to select the top contributors to a measure, typically in line of a general 80/20 rule. For example, to find the top customers that contribute to 80% of the turnover, Customer should be used as field, sum(Turnover) should be used as expression and 80 should be used as percentage.
- **Lock Field**: Locks the selections in the specified field.
- **Lock All**: Locks all values in all fields.
- **Unlock Field**: Unlocks the selections in the specified field.
- **Unlock All**: Unlocks all values in all fields.
- **Unlock and Clear All**: Unlocks all values and clears all selections in all fields.

- **Clear Other Fields:** Clears all related fields except the one specified.
- **Clear All:** Clears all selections except locked ones.
- **Clear Field:** Clears a specific field.

### Layout

- **Activate Object:** Activates the object specified by **Object ID**. This function does not work in Ajax client.
- **Activate Sheet:** Activates the sheet specified by **Sheet ID**.
- **Activate Next Sheet:** Opens the next sheet in the document.
- **Activate Previous Sheet:** Opens the previous sheet in the document.
- **Minimize Object:** Minimizes the object specified by **Object ID**.
- **Maximize Object:** Maximizes the object specified by **Object ID**.
- **Restore Object:** Restores the object specified by **Object ID**.

### Bookmark

- **Apply Bookmark:** Applies a bookmark specified by **Bookmark ID**. If two bookmarks have the same ID, the document bookmark is applied. To apply the server bookmark specify Server\bookmarkID.
- **Create Bookmark:** Creates a bookmark from the current selection. Specify **Bookmark ID** and **Bookmark Name**. Select **Hidden** to create a hidden bookmark.
- **Replace Bookmark:** Replaces the bookmark specified by **Bookmark ID** with the current selection.

### Print

- **Print Object:** Prints the object specified by **Object ID**. Specify the **Printer name** if the object should be sent to another printer than the default printer. (Not available as document and sheet trigger.)
- **Print Sheet:** Prints the sheet specified by **Sheet ID**. (Not available as document and sheet trigger.) This function does not work in AJAX client.
- **Print Report:** Prints the report specified by **Report ID**. Specify the **Printer name** if the report should be sent to another printer than the default printer. Mark the check box **Show Print Dialog** if you want the Windows print dialog to be shown. (Not available as document and sheet trigger.)

### External

Some clients may not handle this setting!

- **Export:** Exports a table containing a specific set of fields, but only those records that are applicable according to the made selection are exported. Click on the **Setup** button on the **Actions** page to open the **Export Action Settings** dialog. This is not available as document or sheet trigger.

*This function does not work in AJAX client.*

- **Launch:** Launches an external program. The following settings can be configured in the **Actions** dialog:
  - **Application:** Click on **Browse...** to find the application that should be launched. (Not available as document and sheet trigger.)

- **Filename:** Enter the path to the file that should be opened with the application specified above. (Not available as document and sheet trigger.)
- **Parameters:** Specify parameters for the command line from which the application is started. (Not available as document and sheet trigger.)
- **Working Directory:** Sets the working directory for the application to be launched. (Not available as document and sheet trigger.)
- **Exit application when QlikView is closed:** Forces the application to be closed when QlikView is exited. (Not available as document and sheet trigger.)

*This function does not work in AJAX client.*

- **Open URL:** You can use **Open URL** to open a URL to a QlikView document from within another QlikView document (document chaining). This setting opens the URL in the default web browser. This function cannot be used as a document and sheet trigger. If using **Open URL**, make sure to enter the document name in the action-string in lower case.

Where possible, use **Open QlikView Document** instead of **Open URL**.

*The use of Javascript in URLs is prevented by default. You can allow Javascript in URLs by changing the `PreventJavascriptInObjectActions` parameter in the `custom.config` file.*

- **Open QlikView Document:** You can use **Open QlikView Document** to open a QlikView document from within another QlikView document (document chaining). This function cannot be used as a document or sheet trigger. For more information, see *Document chaining examples (page 1663)*.
- **Run Macro:** Enter the path and name of the macro to be run. Type any name for which it is possible to later create a macro in the **Edit Module** dialog, or a **calculated expression** for dynamic update.
- **Set Variable:** Assigns a value to the specified variable.
- **Show Information:** Shows the associated information, such as a text file or an image for the field specified by **Field**. This function does not work in AJAX client.
- **Close This Document:** Closes the active QlikView document.
- **Reload:** Performs a reload on the current document. This function does not work both in AJAX client and IE-plugin.
- **Dynamic Update:** Performs a dynamic update of the data in the currently loaded document. The statement for the dynamic update is to be entered in the **Statement** field. The intended usage of Dynamic Update allows a QlikView Administrator to feed limited amounts of data in to a QlikView document from a single source without running a reload of the document. Analysis can then be performed by multiple clients connecting to the QlikView Server.

*The uploaded information is stored in RAM only so any data added or updated using Dynamic Update will be lost if a reload of the document is performed.*

The following grammar describes the possible statements and their components that can be used with the Dynamic Update feature:

- statements ::= statement { “,” statement }
- statement ::= insert\_statement | update\_statement | delete\_statement | begin\_transaction\_statement | commit\_transaction\_statement
- insert\_statement ::= "INSERT" "INTO" ("\*" | table\_name) field\_list "VALUES" value\_list {" , " value\_list } ["KEY" ["AUTO" | (" (" field\_list ")")] ["REPLACE" (["WITH" "ONE"] | "EACH") ]]
- update\_statement ::= "UPDATE" ("\*" | table\_name) set\_clause {" , " | set\_clause } "WHERE" condition ["AUTO" "INSERT"]
- delete\_statement ::= "DELETE" "FROM" ("\*" | table\_name) "WHERE" condition
- begin\_transaction\_statement ::= "BEGIN" ("TRANSACTION" | "TRAN") [trans\_name]
- commit\_transaction\_statement ::= "COMMIT" ["TRANSACTION" | "TRAN"] [trans\_name]
- table\_name ::= identifier | quoted\_name
- field\_list ::= "(" field\_name {" , " field\_name } ")"
- value\_list ::= "(" value {" , " value } ")"
- set\_clause ::= "SET" field\_name "=" any\_valid\_non\_aggregated\_qlikview\_expression
- field\_name ::= identifier | quoted string
- value ::= identifier | any\_qlikview\_number | quoted string
- condition ::= any\_valid\_non\_aggregated\_qlikview\_expression
- identifier ::= any\_qlikview\_identifier
- quoted\_string ::= "[" (^)+ "]"

**Example:**

```
UPDATE AbcTable SET Discount = 123 WHERE AbcField=1
```

*To use this feature, Dynamic Update must be allowed both on the Document and on the Server.*

**Document chaining examples**

You can use **Open QlikView Document** to create document chaining.

The following settings can be applied:

- **Transfer State:** to transfer the selections from the original document to the destination document. The destination document will first be cleared of selections.
- **Apply state on top of current:** to retain the destination document's selections and apply the original document's selections on top of them.

*Using **Apply state on top of current** can return unexpected results if the selections made in the two documents are conflicting.*

- **Open in same Window:** to open the new document in the same browser tab when using the AJAX ZFC client.

*Open QlikView Document action is not supported for non domain users when using the QlikView plug-in.*

QlikView documents: The extension of the destination file must be included. Relative paths to navigate from one QlikView document to another are supported in all clients, as long as the chained documents are stored in the same folder structure (mount).

The following examples show how to write the file path to the destination file:

**Example:** File located in the same folder structure (same mount).

- If the destination file is in the same folder:  
*DestinationDoc.qvw*
- If the destination file is in a sub folder:  
*SubFolder/DestinationDoc.qvw*
- If the destination file is in an upper folder:  
*../DestinationDoc.qvw*
- If the destination file is in an upper and parallel folder:  
*../ParallelFolder/DestinationDoc.qvw*

**Example:** File located in a different folder structure (different mount). The relative path between different mounts is supported in the Ajax client only.

- If the destination file is in a different mount:  
*../DifferentMount/DestinationDoc.qvw*

**Example:** Using the mount path to point to a QlikView document. Setting the path to mounted folders is supported in the Ajax client only.

- If the destination file is in the same mounted folder:  
*\Mount\DestinationDoc.qvw*
- If the destination file is in a different mounted folder:  
*\DifferentMount\DestinationDoc.qvw*

*Document chaining with mounted folders does not work with the QlikView plug-in.*

**Example:** Using the absolute path to point to a QlikView document. The use of absolute paths for document chaining is supported in the Ajax client and in QlikView Desktop.

- Absolute path to the Local Root folder or mount:  
*C:\...\DestinationDoc.qvw*
- Absolute path to a Network Share:  
*\\SharedStorage\...\DestinationDoc.qvw*

QlikView apps in the Qlik Sense Cloud hub: you need the AppId, not the path. Apps need to be prepared and updated in QlikView Desktop. The AppId is found in the URL when the app is open in the hub.

### Example

If the URL is

*https://qcs.us.qlikcloud.com/qv/opendoc.htm?document=1cc71b323f172f93a8121ce1456cdg*. Then the Appld is *1cc71b323f172f93a8121ce1456cdg*.

## Text Object Properties: Presentation

### Representation

The text in the text object can be interpreted as a reference to an image in memory or on disk. When selecting **Text** the contents of the text object will always be interpreted and displayed as text. When selecting **Image**, QlikView will try to interpret the text contents as a reference to an image. The reference may be a path to an image file on disk or inside the qvw document. It can also be an info function linked to a field containing image info. If QlikView cannot interpret the text contents as a valid reference to an image, the text itself will be displayed. Click  to open the popup.

### Formatting

The following formatting options are available:

- **No Stretch**: Displays the image without stretching. This may cause parts of the picture to be invisible or only part of the object to be filled.
- **Fill**: The image is stretched to fit the object area without keeping the aspect ratio of the image.
- **Keep Aspect**: The image is stretched as far as possible to fill the object area while keeping the aspect ratio.
- **Fill with Aspect**: The image is stretched to fill the object area in both directions while keeping the aspect ratio.

### Horizontal

**Left**, **Centered** or **Right** alignment of the text or image.

### Vertical

**Top**, **Centered** or **Bottom** alignment of the text or image.

### Text Margin

Sets the margin between the outer borders of the text object and the text itself.

### Show Horizontal Scrollbar

If this check box is marked, a horizontal scroll bar will be added to the text object when its text content is too wide to be displayed within the given area.

### Show Vertical Scrollbar

If this check box is marked, a vertical scroll bar will be added to the text object when its text content is too long to be displayed within the given area

## Background Style

### Color

Sets the background to a color, either a solid color or a gradient. Click  to choose the color.

### Image

Sets an image as background. Click  to browse for an image. Click  to open the **Image** popup.

- **No Stretch:** Displays the image without stretching. This may cause parts of the picture to be invisible or only part of the object to be filled.
- **Fill:** The image is stretched to fit the object area without keeping the aspect ratio of the image.
- **Keep Aspect:** The image is stretched as far as possible to fill the object area while keeping the aspect ratio.
- **Fill with Aspect:** The image is stretched to fill the object area in both directions while keeping the aspect ratio.
- **Horizontal:** **Left**, **Centered** or **Right** alignment.
- **Vertical:** **Top**, **Centered** or **Bottom** alignment.
- **Transparency:** Set the level of transparency by entering a value or by dragging the slider. At 100% the background will be completely transparent.

## Background Transparency

Sets the degree of transparency of the text object background. At 100% the background will be completely transparent.

### More.../Less...

Click this button to expand/collapse the foldout that contains additional tabs.

## Styles

Presentation styles

| Option           | Description                                                                                                                                                                                                                                                          |

| Active Caption   | To set the background color for the active caption click  . To set the text color click  .    |
| Inactive Caption | To set the background color for the inactive caption click  . To set the text color click  . |

| Option          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Use Border      | Mark this check box in order to use a border around the sheet object. Click  to set the color of the border.                                                                                                                                                                                                                                                                                                                                                                                                      |
| Border Width    | Specify the width of the border in the input field, or drag the slider to the desired width. The width is specified in pixels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Rounded Corners | Click  to open the <b>Rounded Corners</b> popup.<br><br><div style="border: 1px solid gray; padding: 5px; margin: 5px 0;">  <b><i>Rounded Corners is only available if you have selected <b>Advanced Styling Mode</b> in Document Properties: General.</i></b> </div> <p>Select <b>Fixed</b> or <b>Relative</b> roundness of the corners, and which corners to be affected. Also select <b>Squareness</b> by entering a value.</p> |

## Text Object Properties: Caption

### Caption

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.

The value may be entered as a calculated formula.

Click  to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

### More.../Less...

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!

- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!
- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Maximize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.
- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.  
Click  to open the popup.
- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Text Object Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.

- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.
- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click  , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.20 Line/Arrow Object - AJAX/WebView

The Line/Arrow object is a sheet object that draws a line or an arrow in the layout. A line can, for example make the layout clearer by separating the documents into sections.

### Line/Arrow: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

Line/Arrow Object - AJAX/WebView commands

| Command       | Details                                                         |
|---------------|-----------------------------------------------------------------|
| Properties... | Opens the <b>Properties</b> dialog for the active sheet object. |
| Notes         | Allows creating and sharing notes about the current object.     |

| Command       | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Copy          | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                                                                                                 |
| Print...      | Opens the selected sheet object(s) in tabular format in another browser window.<br><br>Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                           |
| Send to Excel | Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Clicking on the  icon in the object caption (if shown) produces the same result. |
| Export...     | Opens the <b>Save as</b> dialog where path, file name and (table) file type for the exported data content can be specified.                                                                                                                                                                                                                                                                                                                                        |
| Delete        | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Line/Arrow Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. This command can also be invoked by the following keyboard shortcut: Alt+Enter. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

### Line Orientation

Sets the direction of the line/arrow to horizontal, vertical or one of two diagonal modes.

### Arrow Style

Choose how the arrowhead should be drawn.

### Actions

To add an action click . The **Action Settings** popup for the new action opens instantly. It is also possible to select an action in the drop-down and to click  to edit. The  icon moves the items in the list. The  icon removes the items from the list.

### Actions Settings Popup

- **Type:** Choose a **Type** in the drop-down list.
- **Subtype:** Choose a **Subtype** in the drop-down list. The subtypes available depend on the **Action Type** chosen.

## Action Types and Actions

- **Selection:**
  - **Select in Field:** Selects the values and fields that are specified. In the **Search String** you can specify a search mask, e.g. (A|B) will select both A and B.
  - **Select Excluded:** Selects the excluded values in the specified field.
  - **Select Possible:** Selects the possible values in the specified field.
  - **Toggle Select:** Toggles between the current selection and the specified **Field** and **Search String**. In the **Search String** you can specify a search mask, e.g. (A|B) will select both A and B.
  - **Forward:** Goes one step forward in the list of selections.
  - **Back:** Goes back one step in the list of selections.
  - **Pareto Select:** Makes a pareto selection in the specified field based on an expression and percentage. This type of selection is used to select the top contributors to a measure, typically in line of a general 80/20 rule. For example, to find the top customers that contribute to 80% of the turnover, Customer should be used as field, sum(Turnover) should be used as expression and 80 should be used as percentage.
  - **Lock Field:** Locks the selections in the specified field.
  - **Lock All:** Locks all values in all fields.
  - **Unlock Field:** Unlocks the selections in the specified field.
  - **Unlock All:** Unlocks all values in all fields.
  - **Unlock and Clear All:** Unlocks all values and clears all selections in all fields.
  - **Clear Other Fields:** Clears all related fields except the one specified.
  - **Clear All:** Clears all selections except locked ones.
  - **Clear Field:** Clears a specific field.
- **Layout:**
  - **Activate Object:** Activates the object specified by **Object ID**. This function does not work in Ajax client.
  - **Activate Sheet:** Activates the sheet specified by **Sheet ID**.
  - **Activate Next Sheet:** Opens the next sheet in the document.
  - **Activate Previous Sheet:** Opens the previous sheet in the document.
  - **Minimize Object:** Minimizes the object specified by **Object ID**.
  - **Maximize Object:** Maximizes the object specified by **Object ID**.
  - **Restore Object:** Restores the object specified by **Object ID**.
- **Bookmark:**
  - **Apply Bookmark:** Applies a bookmark specified by **Bookmark ID**. If two bookmarks have the same ID, the document bookmark is applied. To apply the server bookmark specify Server\bookmarkID.
  - **Create Bookmark:** Creates a bookmark from the current selection. Specify **Bookmark ID** and **Bookmark Name**. Select **Hidden** to create a hidden bookmark.

- **Replace Bookmark:** Replaces the bookmark specified by **Bookmark ID** with the current selection.
- **Print:**
  - **Print Object:** Prints the object specified by **Object ID**. Specify the **Printer name** if the object should be sent to another printer than the default printer. (Not available as document and sheet trigger.)
  - **Print Sheet:** Prints the sheet specified by **Sheet ID**. (Not available as document and sheet trigger.) This function does not work in AJAX client.
  - **Print Report:** Prints the report specified by **Report ID**. Specify the **Printer name** if the report should be sent to another printer than the default printer. Mark the check box **Show Print Dialog** if you want the Windows print dialog to be shown. (Not available as document and sheet trigger.)
- **External:** Some clients may not handle this setting!
  - **Export:** Exports a table containing a specific set of fields, but only those records that are applicable according to the made selection are exported. Click on the **Setup** button on the **Actions** page to open the **Export Action Settings** dialog. This is not available as document or sheet trigger.

*This function does not work in AJAX client.*

- **Launch:** Launches an external program. The following settings can be configured in the **Actions** dialog:
  - **Application:** Click on **Browse...** to find the application that should be launched. (Not available as document and sheet trigger.)
  - **Filename:** Enter the path to the file that should be opened with the application specified above. (Not available as document and sheet trigger.)
  - **Parameters:** Specify parameters for the command line from which the application is started. (Not available as document and sheet trigger.)
  - **Working Directory:** Sets the working directory for the application to be launched. (Not available as document and sheet trigger.)
  - **Exit application when QlikView is closed:** Forces the application to be closed when QlikView is exited. (Not available as document and sheet trigger.)

*This function does not work in AJAX client.*

- **Open URL:** You can use **Open URL** to open a URL to a QlikView document from within another QlikView document (document chaining). This setting opens the URL in the default web browser. This function cannot be used as a document and sheet trigger. If using **Open URL**, make sure to enter the document name in the action-string in lower case. Where possible, use **Open QlikView Document** instead of **Open URL**.

*The use of Javascript in URLs is prevented by default. You can allow Javascript in URLs by changing the `PreventJavascriptInObjectActions` parameter in the custom.config file.*

- **Open QlikView Document:** You can use **Open QlikView Document** to open a QlikView document from within another QlikView document (document chaining). This function cannot be used as a document or sheet trigger. For more information, see *Document chaining examples* (page 1674).
- **Run Macro:** Enter the path and name of the macro to be run. Type any name for which it is possible to later create a macro in the **Edit Module** dialog, or a **calculated expression** for dynamic update.
- **Set Variable:** Assigns a value to the specified variable.
- **Show Information:** Shows the associated information, such as a text file or an image for the field specified by **Field**. This function does not work in AJAX client.
- **Close This Document:** Closes the active QlikView document.
- **Reload:** Performs a reload on the current document. This function does not work both in AJAX client and IE-plugin.
- **Dynamic Update:** Performs a dynamic update of the data in the currently loaded document. The statement for the dynamic update is to be entered in the **Statement** field. The intended usage of Dynamic Update allows a QlikView Administrator to feed limited amounts of data in to a QlikView document from a single source without running a reload of the document. Analysis can then be performed by multiple clients connecting to the QlikView Server.

*The uploaded information is stored in RAM only so any data added or updated using Dynamic Update will be lost if a reload of the document is performed.*

The following grammar describes the possible statements and their components that can be used with the Dynamic Update feature:

- `statements ::= statement { ";" statement }`
- `statement ::= insert_statement | update_statement | delete_statement | begin_transaction_statement | commit_transaction_statement`
- `insert_statement ::= "INSERT" "INTO" ("*" | table_name) field_list "VALUES" value_list { "," value_list } ["KEY" ["AUTO" | (" (" field_list ")") ] ["REPLACE" (["WITH" "ONE"] | "EACH") ]]`
- `update_statement ::= "UPDATE" ("*" | table_name) set_clause { "," | set_clause } "WHERE" condition ["AUTO" "INSERT"]`
- `delete_statement ::= "DELETE" "FROM" ("*" | table_name) "WHERE" condition`
- `begin_transaction_statement ::= "BEGIN" ("TRANSACTION" | "TRAN") [trans_name]`
- `commit_transaction_statement ::= "COMMIT" ["TRANSACTION" | "TRAN"] [trans_name]`
- `table_name ::= identifier | quoted_name`

- `field_list ::= "(" field_name {"," field_name} ")"`
- `value_list ::= "(" value {"," value} ")"`
- `set_clause ::= "SET" field_name "=" any_valid_non_aggregated_qlikview_expression`
- `field_name ::= identifier | quoted string`
- `value ::= identifier | any_qlikview_number | quoted string`
- `condition ::= any_valid_non_aggregated_qlikview_expression`
- `identifier ::= any_qlikview_identifier`
- `quoted_string ::= "[" [^"]+ "]"`

**Example:**

```
UPDATE AbcTable SET Discount = 123 WHERE AbcField=1
```

*To use this feature, Dynamic Update must be allowed both on the Document and on the Server.*

**Document chaining examples**

You can use **Open QlikView Document** to create document chaining.

The following settings can be applied:

- **Transfer State:** to transfer the selections from the original document to the destination document. The destination document will first be cleared of selections.
- **Apply state on top of current:** to retain the destination document's selections and apply the original document's selections on top of them.

*Using **Apply state on top of current** can return unexpected results if the selections made in the two documents are conflicting.*

- **Open in same Window:** to open the new document in the same browser tab when using the AJAX ZFC client.

*Open QlikView Document action is not supported for non domain users when using the QlikView plug-in.*

QlikView documents: The extension of the destination file must be included. Relative paths to navigate from one QlikView document to another are supported in all clients, as long as the chained documents are stored in the same folder structure (mount).

The following examples show how to write the file path to the destination file:

**Example:** File located in the same folder structure (same mount).

- If the destination file is in the same folder:  
*DestinationDoc.qvw*

- If the destination file is in a sub folder:  
*SubFolder/DestinationDoc.qvw*
- If the destination file is in an upper folder:  
*../DestinationDoc.qvw*
- If the destination file is in an upper and parallel folder:  
*../ParallelFolder/DestinationDoc.qvw*

**Example:** File located in a different folder structure (different mount). The relative path between different mounts is supported in the Ajax client only.

- If the destination file is in a different mount:  
*../DifferentMount/DestinationDoc.qvw*

**Example:** Using the mount path to point to a QlikView document. Setting the path to mounted folders is supported in the Ajax client only.

- If the destination file is in the same mounted folder:  
*\Mount\DestinationDoc.qvw*
- If the destination file is in a different mounted folder:  
*\DifferentMount\DestinationDoc.qvw*

*Document chaining with mounted folders does not work with the QlikView plugin.*

**Example:** Using the absolute path to point to a QlikView document. The use of absolute paths for document chaining is supported in the Ajax client and in QlikView Desktop.

- Absolute path to the Local Root folder or mount:  
*C:\...\DestinationDoc.qvw*
- Absolute path to a Network Share:  
*\\SharedStorage\...\DestinationDoc.qvw*

QlikView apps in the Qlik Sense Cloud hub: you need the AppId, not the path. Apps need to be prepared and updated in QlikView Desktop. The AppId is found in the URL when the app is open in the hub.

### Example

If the URL is

*https://qcs.us.qlikcloud.com/qv/opendoc.htm?document=1cc71b323f172f93a8121ce1456cdg.*

Then the AppId is *1cc71b323f172f93a8121ce1456cdg.*

## Line/Arrow Properties: Presentation

This section describes **Presentation** properties.

### Line Style

Set the style of the line to **Solid**, **Dashed** or **Dotted**.

## Line Weight

Sets the weight of the line.

## Background Color

Sets the background to a color, either a solid color or a gradient. Click  to choose the color.

## Background Image

Sets an image as background. Click  to browse for an image. Click  to open the **Image** popup.

## Image Popup

- **No Stretch:** Displays the image without stretching. This may cause parts of the picture to be invisible or only part of the object to be filled.
- **Fill:** The image is stretched to fit the object area without keeping the aspect ratio of the image.
- **Keep Aspect:** The image is stretched as far as possible to fill the object area while keeping the aspect ratio.
- **Fill with Aspect:** The image is stretched to fill the object area in both directions while keeping the aspect ratio.
- **Horizontal:** **Left**, **Centered** or **Right** alignment.
- **Vertical:** **Top**, **Centered** or **Bottom** alignment.
- **Transparency:** Set the level of transparency by entering a value or by dragging the slider. At 100% the background will be completely transparent.

## More.../Less...

This section describes **Styles** in **More.../Less...**

## Styles

### Styles:

- **Line Color:** To set the line color click .
- **Caption Font:** To set the caption font type click .
- **Active Caption:** To set the background color for the active caption click . To set the text color click .
- **Inactive Caption:** To set the background color for the inactive caption click . To set the text color click .
- **Use Border:** Mark this check box in order to use a border around the sheet object. Click  to set the color of the border.

- **Border Width:** Specify the width of the border in the input field, or drag the slider to the desired width. The width is specified in pixels.
- **Rounded Corners:** Click  to open the **Rounded Corners** popup.

*Rounded Corners is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.*

Rounded Corners Popup

Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected. Also select **Squareness** by entering a value.

## Line/Arrow Properties: Caption

This section describes **Caption** properties.

### Caption properties

This section describes **Caption** properties options.

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.  
The value may be entered as a calculated formula.

Click  to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

### Icon Caption properties

This section describes **Icon Caption** properties.

#### More.../Less...

- Icons in Caption:
  - **Menu:** Opens the object menu.
  - **Clear:** Clears all the current selections in the active sheet object.
  - **Print:** Opens the selected sheet object(s) in tabular format in another browser window.  
Some clients may not handle this setting!

- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!
- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Maximize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.
- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects. Click  to open the popup.
- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Line/Arrow Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.

- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.
- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.  
To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.21 Calendar Object - AJAX/Webview

The Calendar object provides alternative means to select values in QlikView fields or enter values in QlikView variables. The calendar object has two different modes.

It is possible to select multiple dates if the **Multi Value** option is checked in the calendar object's **Properties** menu. To select multiple dates, click on each date required to highlight it. To deselect dates, click on each highlighted date that is not required.

### Calendar: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

Calendar: Object Menu commands

| Command       | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Properties... | Opens the <b>Properties</b> dialog for the active sheet object.                                                                                                                                                                                                                                                                                                                                                                                                    |
| Notes         | Allows creating and sharing notes about the current object.                                                                                                                                                                                                                                                                                                                                                                                                        |
| Copy          | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                                                                                                 |
| Print...      | Opens the selected sheet object(s) in tabular format in another browser window.<br><br>Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                           |
| Send to Excel | Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Clicking on the  icon in the object caption (if shown) produces the same result. |
| Export...     | Opens the <b>Save as</b> dialog where path, file name and (table) file type for the exported data content can be specified.                                                                                                                                                                                                                                                                                                                                        |
| Minimize      | Iconizes the object. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if minimizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                                                                                              |
| Restore       | Restores a minimized or maximized object to its previous size and location. Double-clicking the icon of a minimized object or clicking the  icon in the object caption (if shown) of a maximized object produces the same result. This command is available only for minimized or maximized objects.                                                                           |
| Maximize      | Enlarges the object to fill the sheet. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if maximizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                                                                           |
| Delete        | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Calendar Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

## Field

Select the field you want to include in the calendar in the drop-down. Choose whether the object should be connected to a **Field** or to a **Variable**.

## Variable(s)

Select the variable in the drop-down menu. Choose whether the object should be connected to a **Field** or to a **Variable**.

## Calendar Mode

- **Single Value**: For selection of a single value.
- **Multi Value (Ranged)**: For selection of a range of values. Multi value selection is not available in Ajax client.

## More.../Less...

This section describes the tabs available inside More.../Less...

### General Tab

When **Field** is selected **Min Value** and **Max Value** are disabled and when **Variable** is selected **Override Locked Field** is disabled.

- **Min Value**: Set a fixed minimum value for the object. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Max Value**: Set a fixed maximum value for the object. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Override Locked Field**: Selections can be made via the calendar object in a field even if the field is locked. The field will still be locked for logical changes stemming from selections in other fields.

### Number Format Tab

Each field has a default number format which can be set in the Document Properties: Number page. It is however possible to use a separate number format for an individual sheet object. This property page applies to the active object and contains the following controls for formatting values: **Override Default Settings**Select to override the default settings for the active object.**Number** Choose a number format from the alternatives below.

- **Mixed**: Both numbers and text. Numbers are shown in original format.
- **Number**: Shows numeric values with the number of digits set in the **Precision** field.
- **Integer**: Shows numeric values as integers.
- **Fixed to**: Shows numeric values as decimal values with the number of decimal digits set in the **Decimals** field.
- **Money**: Shows values in the format set in the **Format Pattern** field. The default format is the Windows Currency setting.
- **Date**: Shows values that can be interpreted as dates in the format set in the **Format Pattern** field.
- **Time**: Shows values that can be interpreted as time in the format set in the **Format Pattern** field.
- **Timestamp**: Shows values that can be interpreted as date + time in the format set in the **Format Pattern** field.
- **Interval**: Shows time as sequential time increments (e.g. format = mm shows the value as the number of minutes since calendar start (1899:12:30:24:00)).

**Format Pattern:** The format code that further specifies the display format of the field.

- **ISO:** sets the format to the ISO standard. Only valid for **Date**, **Time**, **Timestamp** and **Interval**.
- **Sys:** sets the format to the system settings.
- **Precision:** The number of digits that will be displayed.
- **Decimals:** Sets the number of decimals included.
- **Decimals Separator:** Sets the symbol for decimal separators.
- **Thousand Separator:** Sets the symbol for thousand separators.
- **In Percent:** Shows formatting in percentage instead of absolute numbers. The setting is only available for **Number**, **Integer** and **Fixed to**.
- **Preview:** Shows a preview of the number format specified above.

## Calendar Properties: Presentation

This section describes the Presentation properties for Calendar.

### Background Color

Sets the background to a color, either a solid color or a gradient. Click  to choose the color.

### Background Image

Sets an image as background. Click  to browse for an image. Click  to open the **Image** popup.

### Image Popup

The Image Popup contains several formatting options:

- **No Stretch:** Displays the image without stretching. This may cause parts of the picture to be invisible or only part of the object to be filled.
- **Fill:** The image is stretched to fit the object area without keeping the aspect ratio of the image.
- **Keep Aspect:** The image is stretched as far as possible to fill the object area while keeping the aspect ratio.
- **Fill with Aspect:** The image is stretched to fill the object area in both directions while keeping the aspect ratio.
- **Horizontal:** **Left**, **Centered** or **Right** alignment.
- **Vertical:** **Top**, **Centered** or **Bottom** alignment.
- **Transparency:** Set the level of transparency by entering a value or by dragging the slider. At 100% the background will be completely transparent.

### More.../Less

More.../Less... contains the following styles:

- **Text:** To set the text color click . To set the font type click .
- **Caption Font:** To set the caption font type click .
- **Active Caption:** To set the background color for the active caption click . To set the text color click .
- **Inactive Caption:** To set the background color for the inactive caption click . To set the text color click .
- **Use Border:** Mark this check box in order to use a border around the sheet object. Click  to set the color of the border.
- **Border Width:** Specify the width of the border in the input field, or drag the slider to the desired width. The width is specified in pixels.
- **Rounded Corners:** Click  to open the **Rounded Corners** popup.

*Rounded Corners is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.*

- **Rounded Corners Popup:** Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected. Also select **Squareness** by entering a value.

## Calendar Properties: Caption

This section describes the Caption properties for Calendar

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.  
The value may be entered as a calculated formula.

Click  to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

## Icon caption

Icon caption has one property, **More.../Less...**, which contains several options that will be outlined in this section.

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!
- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Maximize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.
- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.  
Click  to open the popup.
- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Calendar Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.
- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.22 Slider Object - AJAX/WebView

The Slider object provides alternative means to select values in QlikView fields or enter values in QlikView variables. The slider object has two different modes.

## Slider: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

Object Menu properties

| Property      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Properties... | Opens the <b>Properties</b> dialog for the active sheet object.                                                                                                                                                                                                                                                                                                                                                                                                      |
| Notes         | Allows creating and sharing notes about the current object.                                                                                                                                                                                                                                                                                                                                                                                                          |
| Copy          | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                                                                                                   |
| Print...      | Opens the selected sheet object(s) in tabular format in another browser window.<br><br>Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                             |
| Send to Excel | Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Clicking on the  icon in the object caption (if shown) produces the same result. |
| Export...     | Opens the <b>Save as</b> dialog where path, file name and (table) file type for the exported data content can be specified.                                                                                                                                                                                                                                                                                                                                          |
| Minimize      | Iconizes the object. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if minimizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                                                                                                |
| Restore       | Restores a minimized or maximized object to its previous size and location. Double-clicking the icon of a minimized object or clicking the  icon in the object caption (if shown) of a maximized object produces the same result. This command is available only for minimized or maximized objects.                                                                            |
| Maximize      | Enlarges the object to fill the sheet. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if maximizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                                                                             |
| Delete        | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Slider Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

## Field

Select the field you want to show in the slider in the drop-down. Choose whether the object should be connected to a **Field** or to a **Variable**.

## Variable(s)

Select the variable in the drop-down menu. Choose whether the object should be connected to a **Field** or to a **Variable**.

## Slider Mode

- **Single Value**: For selection of a single value.
- **Multi Value (Ranged)**: For selection of a range of values.

## Value Mode

- **Discrete**: For selection of discrete values.
- **Continuous/Numeric**: For selection of continuous/numeric values (unavailable for Single Value mode with Field data).

## More.../Less...

Click this button to expand/collapse the foldout that contains additional tabs.

## General

When **Field** is selected **Min value**, **Max Value** and **Static Steps** are disabled and when **Variable** is selected are they enabled.

- **Min Value**: Set a fixed minimum value for the object. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Max Value**: Set a fixed maximum value for the object. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Step**: Sets a fixed interval for tic marks on the axis. If this setting results in more than 100 tick marks, the value used will be modified. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Move with Selection**: Only available in slider mode. Override Locked FieldSelections can be made via the slider object in a field even if the field is locked. The field will still be locked for logical changes stemming from selections in other fields.
- **Number**: Each field has a default number format which can be set in the Document Properties: Number page. It is however possible to use a separate number format for an individual sheet object. This property page applies to the active object and contains the following controls for formatting values:
  - **Override Default Settings**: Select to override the default settings for the active object.
  - **Number Format**: Choose a number format from the alternatives below.
  - **Mixed**: Both numbers and text. Numbers are shown in original format.
  - **Number**: Shows numeric values with the number of digits set in the **Precision** field.

- **Integer:** Shows numeric values as integers.
- **Fixed to:** Shows numeric values as decimal values with the number of decimal digits set in the **Decimals** field.
- **Money:** Shows values in the format set in the **Format Pattern** field. An example of this format is shown in the **Preview** field. The default format is the Windows Currency setting.
- **Date:** Shows values that can be interpreted as dates in the format set in the **Format Pattern** field. An example of this format is shown in the **Preview** field.
- **Time:** Shows values that can be interpreted as time in the format set in the **Format Pattern** field. An example of this format is shown in the **Preview** field.
- **Timestamp:** Shows values that can be interpreted as date + time in the format set in the **Format Pattern** field. An example of this format is shown in the **Preview** field.
- **Interval:** Shows time as sequential time increments (e.g. format = mm shows the value as the number of minutes since calendar start (1899:12:30:24:00)).Format PatternThe format code that further specifies the display format of the field.
- **ISO:** Sets the format to the ISO standard. Only valid for **Date**, **Time**, **Timestamp**, and **Interval**.
- **Sys:** Sets the format to the system settings.
  - **Precision:** The number of digits that will be displayed.
  - **Decimals:** Sets the number of decimals included.
  - **Decimal Separator:** Sets the symbol for decimal separators.
  - **Thousand Separator:** Sets the symbol for thousand separators.
  - **In Percent:** Shows formatting in percentage instead of absolute numbers. The setting is only available for **Number**, **Integer**, and **Fixed to**.
  - **Preview:** Shows a preview of the format code specified above.

## Slider Properties: Presentation

This section describes **Slider** properties.

### Background Color

Sets the background to a color, either a solid color or a gradient. Click  to choose the color.

### Background Image

Sets an image as background. Click  to browse for an image. Click  to open the **Image** popup.

### Image Popup

**No Stretch:** Displays the image without stretching. This may cause parts of the picture to be invisible or only part of the object to be filled.**Fill:** The image is stretched to fit the object area without keeping the aspect ratio of the image.**Keep Aspect:** The image is stretched as far as possible to fill the object area while keeping the aspect ratio.**Fill with Aspect:** The image is stretched to fill the object area in both directions while keeping the aspect ratio.**Horizontal:** **Left**, **Centered** or **Right** alignment.**Vertical:** **Top**, **Centered** or **Bottom** alignment.**Transparency:** Set the level of transparency by entering a value or by dragging the slider. At 100% the background will be completely transparent.

## More.../Less...

This section describes **More.../Less...** properties.

### Styles

- **Text:** To set the text color click . To set the font type click .
- **Caption Font:** To set the caption font type click .
- **Active Caption:** To set the background color for the active caption click . To set the text color click .
- **Inactive Caption:** To set the background color for the inactive caption click . To set the text color click .
- **Use Border:** Mark this check box in order to use a border around the sheet object. Click  to set the color of the border.
- **Border Width:** Specify the width of the border in the input field, or drag the slider to the desired width. The width is specified in pixels.
- **Rounded Corners:** Click  to open the **Rounded Corners** popup.

***Rounded Corners** is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.*

- **Rounded Corners Popup:** Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected. Also select **Squareness** by entering a value.

## Slider Properties: Caption

This section describes **Slider** properties.

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.

The value may be entered as a calculated formula.

Click  to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.

- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

### More.../Less...

This section describes **More.../Less...** properties.

### Icons in Caption

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!
- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Maximize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.
- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.  
Click  to open the popup.
- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Slider Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.
- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click  , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.23 Bookmark Object - AJAX/Webview

This object is used to display and select selection bookmarks. Bookmarks can be searched by name or selected from the drop-down. Depending on its configuration it can also be used for adding new bookmarks or deleting old ones. It basically offers the same options as the Bookmark menu but can be positioned on the sheet as a sheet object.

### Bookmark: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

Bookmark: Object Menu commands

| Command         | Details                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Properties...   | Opens the <b>Properties</b> dialog for the active sheet object.                                                                                                                                                                                                                                                                                                                          |
| Notes           | Allows creating and sharing notes about the current object.                                                                                                                                                                                                                                                                                                                              |
| Copy            | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                       |
| Add Bookmark    | Saves the current selections as a bookmark.                                                                                                                                                                                                                                                                                                                                              |
| Remove Bookmark | Removes the current bookmark                                                                                                                                                                                                                                                                                                                                                             |
| Minimize        | Iconizes the object. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if minimizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                    |
| Restore         | Restores a minimized or maximized object to its previous size and location. Double-clicking the icon of a minimized object or clicking the  icon in the object caption (if shown) of a maximized object produces the same result. This command is available only for minimized or maximized objects. |
| Maximize        | Enlarges the object to fill the sheet. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if maximizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                 |
| Delete          | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                                                                              |

### Bookmark Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

## Add Button

Type the text that will be displayed on the **Add Bookmark** button. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

## Remove Button

Type the text that will be displayed on the **Remove Bookmark** button. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

## Bookmark Properties: Presentation

### Presentation

#### Background Color

Sets the background to a color, either a solid color or a gradient. Click  to choose the color.

#### Background Image

Sets an image as background. Click  to browse for an image. Click  to open the **Image** popup.

- **No Stretch:** Displays the image without stretching. This may cause parts of the picture to be invisible or only part of the object to be filled.
- **Fill:** The image is stretched to fit the object area without keeping the aspect ratio of the image.
- **Keep Aspect:** The image is stretched as far as possible to fill the object area while keeping the aspect ratio.
- **Fill with Aspect:** The image is stretched to fill the object area in both directions while keeping the aspect ratio.
- **Horizontal:** **Left**, **Centered** or **Right** alignment.
- **Vertical:** **Top**, **Centered** or **Bottom** alignment.
- **Transparency:** Set the level of transparency by entering a value or by dragging the slider. At 100% the background will be completely transparent.

### More.../Less...

- Styles:
  - **Text:** To set the font type click .
  - **Add Button:** To set the font color for the Add button click .
  - **Remove Button:** To set the font color for the Remove button click .
  - **Caption Font:** To set the caption font type click .
  - **Active Caption:** To set the background color for the active caption click . To set the text color click .

- **Inactive Caption:** To set the background color for the inactive caption click . To set the text color click .
- **Use Border:** Mark this check box in order to use a border around the sheet object. Click  to set the color of the border.
- **Border Width:** Specify the width of the border in the input field, or drag the slider to the desired width. The width is specified in pixels.
- **Rounded Corners:** Click  to open the **Rounded Corners** popup.

***Rounded Corners** is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.*

Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected. Also select **Squareness** by entering a value.

## Bookmark Properties: Caption

### Caption

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.  
The value may be entered as a calculated formula.

Click  to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

### More.../Less...

#### Icons in Caption

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!

- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!
- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Maximize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.
- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.  
Click  to open the popup.
- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Bookmark Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By

deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.

- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.
- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.24 Search Object - AJAX/Webview

Search objects can be used for searching for information anywhere in the document.

### Search Object: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

Object Menu properties

| Property      | Description                                                     |
|---------------|-----------------------------------------------------------------|
| Properties... | Opens the <b>Properties</b> dialog for the active sheet object. |

| Property      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes         | Allows creating and sharing notes about the current object.                                                                                                                                                                                                                                                                                                                                                                                                        |
| Copy          | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                                                                                                 |
| Print...      | Opens the selected sheet object(s) in tabular format in another browser window.<br><br>Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                           |
| Send to Excel | Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Clicking on the  icon in the object caption (if shown) produces the same result. |
| Export...     | Opens the <b>Save as</b> dialog where path, file name and (table) file type for the exported data content can be specified.                                                                                                                                                                                                                                                                                                                                        |
| Minimize      | Iconizes the object. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if minimizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                                                                                                |
| Restore       | Restores a minimized or maximized object to its previous size and location. Double-clicking the icon of a minimized object or clicking the  icon in the object caption (if shown) of a maximized object produces the same result. This command is available only for minimized or maximized objects.                                                                           |
| Maximize      | Enlarges the object to fill the sheet. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if maximizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                                                                           |
| Delete        | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Search Object Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

## Sort by Applicability

Sorts the fields according to whether they contain possible field values. Fields lacking possible field values are dynamically moved down if this check box is marked.

## Filed Sorting

Sets the sort order of the object.

## Mode

Sets which fields should be searchable.

## Search Object Properties: Presentation

This section describes **Search Object** properties.

### Include Excluded

Includes values that have been excluded by selections in the search.

### Highlight Substring

The search string so far will be highlighted in the matches.

### Collapse when results in field exceeds

Limit the number of displayed matches in each field.

### Text in Search Field

Enter the text that should be visible in the search object before you enter a search string.

### More.../Less...

This section describes **More.../Less...** properties.

### Style

- Style: To set the font type click .
- Caption Font: To set the caption font type click .
- Active Caption: To set the background color for the active caption click . To set the text color click .
- Inactive Caption: To set the background color for the inactive caption click . To set the text color click .
- Use Border: Mark this check box in order to use a border around the sheet object. Click  to set the color of the border.
- Border Width: Specify the width of the border in the input field, or drag the slider to the desired width. The width is specified in pixels.
- Rounded Corners: Click  to open the **Rounded Corners** popup.
  - Rounded Corners Popup: Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected. Also select **Squareness** by entering a value.

**Rounded Corners** is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.

## Search Object Properties: Caption

This section describes **Search Object** properties.

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.

The value may be entered as a calculated formula.

Click *fx* to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

### More.../Less...

This section describes **More.../Less...** properties.

#### Icons in Caption

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!
- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.

- **Allow Minimize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.
- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.  
Click  to open the popup.
- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Search Object Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.
- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.

- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.25 Container Object - AJAX/WebView

The container object can contain all other sheet objects. The objects are grouped together and have common settings for font, layout and caption.

### Container: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

Container: Object Menu commands

| Command       | Details                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Properties... | Opens the <b>Properties</b> dialog for the active sheet object.                                                                                                                                                                                                                                                                                                                          |
| Notes         | Allows creating and sharing notes about the current object.                                                                                                                                                                                                                                                                                                                              |
| Copy          | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                       |
| Minimize      | Iconizes the object. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if minimizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                    |
| Restore       | Restores a minimized or maximized object to its previous size and location. Double-clicking the icon of a minimized object or clicking the  icon in the object caption (if shown) of a maximized object produces the same result. This command is available only for minimized or maximized objects. |

| Command  | Details                                                                                                                                                                                                                                                                                                                                |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Maximize | Enlarges the object to fill the sheet. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if maximizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page. |
| Delete   | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                            |

## Container Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

To add an object to the container click . Select an object in the drop-down. The  icon moves the items in the list. The  icon removes items from the list.

## Container Properties: Presentation

This section describes the properties available for Container Properties: Presentation.

### Container Type

Select **Single Object** or **Grid**. Grid allows viewing and interacting with more than one object at a time in the container object.

*The following properties described in the sections below differ depending on selected **Container Type**.*

### Appearance

The Appearance property provides the following options for customizing the location of objects in a container:

- **Tabs at top:** All objects in the container are displayed as tabs at the top of the container object.
- **Tabs on the left:** All objects in the container are displayed as tabs on the left of the container object.
- **Tabs at bottom:** All objects in the container are displayed as tabs at the bottom of the container object.
- **Tabs on the right:** All objects in the container are displayed as tabs on the right of the container object.
- **Dropdown at top:** All objects in the container are displayed in a drop-down menu at the top of the container object.
- **Hide tabs:** Hides all tabs and only displays the first object in the object list, or the first object with a show condition that returns TRUE.

### Display Object Type Icons

Enable this setting to have icons symbolizing the different sheet objects in the tabs of the container object.

## Columns

The number of columns in the container object.

## Rows

The number of rows in the container object.

## Spacing

Spacing between rows and columns in the container object.

## Background Color

Sets the background to a color, either a solid color or a gradient. Click  to choose the color.

## Background Image

Sets an image as background. Click  to browse for an image. Click  to open the **Image** popup.

- **Image Popup: No Stretch:** Displays the image without stretching. This may cause parts of the picture to be invisible or only part of the object to be filled.**Fill:** The image is stretched to fit the object area without keeping the aspect ratio of the image.**Keep Aspect:** The image is stretched as far as possible to fill the object area while keeping the aspect ratio.**Fill with Aspect:** The image is stretched to fill the object area in both directions while keeping the aspect ratio.**Horizontal: Left, Centered or Right** alignment.**Vertical: Top, Centered or Bottom** alignment.**Transparency:** Set the level of transparency by entering a value or by dragging the slider. At 100% the background will be completely transparent.

## More.../Less...

The following styles are available for configuration:

- **Text:** To set the background color click . To set the text color click . To set the font type click .
- **Caption Font:** To set the caption font type click .
- **Active Caption:** To set the background color for the active caption click . To set the text color click .
- **Inactive Caption:** To set the background color for the inactive caption click . To set the text color click .
- **Use Border:** Mark this check box in order to use a border around the sheet object. Click  to set the color of the border.
- **Border Width:** Specify the width of the border in the input field, or drag the slider to the desired width. The width is specified in pixels.

- **Rounded Corners:** Click  to open the **Rounded Corners** popup.

***Rounded Corners** is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.*

- **Rounded Corners Popup:** Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected. Select **Squareness** by entering a value.

## Container Properties: Caption

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.

The value may be entered as a calculated formula.

Click  to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

## Icon Caption

Icon Caption consists of one property, More.../Less..., which contains several options that will be outlined in this section.

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!

- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Maximize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.
- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.  
Click  to open the popup.
- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Container Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.

- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.26 Bar Chart - AJAX/WebView

The most basic chart type. It displays values as bars of different height.

### Bar Chart: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

Menu commands

| Command       | Details                                                         |
|---------------|-----------------------------------------------------------------|
| Properties... | Opens the <b>Properties</b> dialog for the active sheet object. |
| Notes         | Allows creating and sharing notes about the current object.     |

| Command              | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Detach               | The chart title is appended with the text "(Detached)" and the chart is no longer updated with selections made in the document (though selections may actually still be made from the chart). The command is available only if the chart is attached. By making a copy of a chart and detaching it, you may make direct comparisons between the copy and the original.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Attach               | Attaches a detached chart. The chart becomes dynamically linked to the data. The command is available only if the chart is detached.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Set Reference        | This option sets a chart reference, such as a fixed plot of the chart with the current selections. When further selections are made in the document the reference plot remains, dimmed in the background. Chart axes will be adjusted to always include the maximum of the background data set and the current data set. The current data set is always plotted on top of the reference plot. Some portions of the reference plot may be obscured by the current data set plot. The display of reference chart plots is only possible in some chart types, such as bar charts, line charts, combo charts, radar charts, scatter charts, grid charts and gauge charts with needles. It is not possible to set a reference for a chart that contains a drill-down or a cyclic group. The reference will be lost when closing the document or when reloading data. The maximum number of objects that can be included when using the <b>Set Reference</b> option is 500. |
| Clear Reference      | This command is replaced with the <b>Set Reference</b> command when a reference is set. By choosing it the previously set reference will be cleared and the chart will revert to normal plot mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Clear All Selections | Clears all the current selections in the active sheet object. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Copy                 | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Print...             | Opens the selected sheet object(s) in tabular format in another browser window.<br><br>Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Send to Excel        | Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Export...            | Opens the <b>Save as</b> dialog where path, file name and (table) file type for the exported data content can be specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Command     | Details                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fast Change | Makes it possible to change the current chart into another chart type. Clicking on the  icon in the object caption (if shown) produces the same result. Only available if <b>Fast Type Change in Chart</b> has been enabled on the <b>Caption</b> tab of the <b>Properties</b> dialog.               |
| Minimize    | Iconizes the object. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if minimizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                   |
| Restore     | Restores a minimized or maximized object to its previous size and location. Double-clicking the icon of a minimized object or clicking the  icon in the object caption (if shown) of a maximized object produces the same result. This command is available only for minimized or maximized objects. |
| Maximize    | Enlarges the object to fill the sheet. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if maximizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                 |
| Remove      | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                                                                           |

## Bar Chart Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

### Dimensions

Choose dimensions in the drop-down list. To add a dimension, click . Select a dimension in the drop-down. Use the  icon to move items in the list. The  icon removes items from the list. For more settings, click the **More...** button.

### Dimension

- **Enable Conditional:** Marking this check box hides or shows the dimension dynamically, depending on the value of a condition expression entered, by clicking the  button in the edit box below.
- **Dimension:** Displays the currently selected dimension. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
- **Show Label:** Mark this check box to show a dimension label (the field name) on the x-axis. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
- **Suppress Null Values:** If this check box is marked, the field selected as **Dimension** above will not be displayed in the chart if its value is NULL.
- **Show All Values:** Mark this check box to show all the dimension field values in the chart, including logically excluded values.

- **Show Axis Labels:** Mark this check box to show legend (names of field values) on the x-axis for the selected dimension field.
- **Limit Axis Label Characters:** Mark this check box to limit the length of the dimension value strings to be shown on axes and in the chart legend. Specify the number of characters in the input field, or drag the slider to the desired value. Truncated values will be followed by ... in the chart. This option can be used independently to the other options in this group.
- **Trellis Setting First Dimension:** Marking this check box will enable the trellis chart, where an array of charts that are based on the chart's first dimension are displayed.
- **Fixed Number of Columns:** Enter the number of columns you want the trellis chart to display. Specify the number of columns in the input field, or drag the slider to the desired value.
- **Fixed Number of Rows:** Enter the number of rows you want the trellis chart to display. Specify the number of rows in the input field, or drag the slider to the desired value.
- **Second Dimension:** Enables the second dimension in the trellis chart. If a secondary dimension is used, the first dimension values will be displayed as columns in the trellis matrix, whereas the secondary dimension values will be displayed as rows in the trellis matrix.

## Sort

Sets the sort order of the values in the sheet object. Some sort options may not be available for all sheet objects.

If more than one sort order is specified, the sort order will be state, expression, frequency, numeric, text, load order. **State** refers to the logical state (selected, optional, or excluded).

- **Primary Sort: Y-Value:** Sets whether the dimension values should be sorted according to the numeric value of the y-axis. This option is not available for calculated dimensions. **Frequency:** Sorts the field values by frequency (number of concurrences in the table). **Numeric Value:** Sorts the field values by their numeric values. **Text:** Sorts the field values in alphabetical order. **Load Order:** Sorts the field values by the initial load order.
- **Secondary Sort:**
  - **Frequency:** Sorts the field values by frequency (number of concurrences in the table).
  - **Number Value:** Sorts the field values by their numeric values.
  - **Text:** Sorts the field values in alphabetical order.
  - **Load Order:** Sorts the field values by the initial load order. Sort by Expression Sorts the field values according to the expression entered. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog. Keep Selected on Top Enable this to keep the selected values on top.

## Limits

Restrict which values are displayed using the first expression.

These properties are used to determine how many dimension values are displayed in the chart, according to settings made below.

- **Show only:**

Select this option if you want to show the **First**, **Largest** or **Smallest** x number of values. If this option is set to 5, there will be five values displayed. If the dimension has **Show Others** enabled, the Others segment will take up one of the five display slots.

- The **First** option will return the rows based on the options selected on the **Sort** tab of the property dialog. If the chart is a Straight Table, the rows will be returned based on the primary sort at the time. In other words, a user can change the values display by double-clicking on any column header and making that column the primary sort.
- The **Largest** option returns the rows in descending order based on the first expression in the chart. When used in a Straight Table, the dimension values shown will remain consistent while interactively sorting the expressions. The dimensions values will (may) change when the order of the expressions is changed.
- The **Smallest** option returns the rows in ascending order based on the first expression in the chart. When used in a Straight Table, the dimension values shown will remain consistent while interactively sorting the expressions. The dimensions values will (may) change when the order of the expressions is changed.
- Enter the number of values to display.

The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog. Select **Include Boundary Values** to include the dimension value that contains the comparison value.

- **Show only values that are:** Select this option to display all dimensions values that meet the specified condition for this option. Select to display values based on a percentage of the total, or on an exact amount. The **relative to the total** option enables a relative mode which is similar to the **Relative** option on the **Expressions** tab of the property dialog. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Show only values that accumulate to:** When this option is selected, all rows up to the current row are accumulated, and the result is compared to the value set in the option. The **relative to the total** option enables a relative mode which is similar to the **Relative** option on the **Expressions** tab of the property dialog, and compares the accumulated values (based on first, largest or smallest values) to the overall total. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Show Others:** Enabling this option will produce an **Others** segment in the chart. All dimension values that do not meet the comparison criteria for the display restrictions will be grouped into the **Others** segment. If there are dimensions after the selected dimension, **Collapse Inner Dimensions** will control whether individual values for the subsequent / inner dimensions display on the chart. In the **Label** field, enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text.  
The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog. If there are dimensions after the selected dimension, **Collapse Inner Dimensions** will control whether individual values for the subsequent / inner dimensions display on the chart.
- **Show Total:** The chart will display a total for the selected dimension when this option is enabled. This total behaves differently than the expression total, which is still configured on the **Expressions** tab of the property dialog. **Label:** Enter the name you wish to display in the chart. If no text is

entered, the label will be automatically set to the expression text. The value may be entered as a calculated formula. Click  $fx$  to open the **Edit Expression** dialog.

- **Use Global Grouping Mode:** The option only applies to inner dimensions. When this option is enabled the restrictions will be calculated on the selected dimension only. All previous dimensions will be ignored. If this is disabled, the restrictions are calculated based on all preceding dimensions.

## Axis

- **Show Axis:** Check this box to show the axis.
- **Axis Width:** Enter the width of the axis and its tick marks, or drag the slider to the desired value.
- **Major Label:** Select **Horizontal**, **Vertical** or **Tilted** display of the major labels.
- **Minor Label:** Select **Horizontal**, **Vertical** or **Tilted** display of the minor labels.
- **Show Grid:** Check this box to show a grid in the chart originating from the tick marks of the x-axis. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Show Minor Grid:** Check this box to show minor lines in-between the grid lines. Only available if **Show Grid** is selected. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Stagger Labels:** Select this option to stagger x-axis labels when they become too many to show side by side.
- **Reverse Stagger:** X-axis labels are normally staggered bottom-up from left to right. When marking this check box, the stagger will be reversed to top-down.
- **Continuous X:** Sets the x-axis to be continuous, i.e. it will be interpreted numerically and shown with numerically correct intervals.
- **Force 0:** Fixes the lower edge of the chart to zero on the y-axis. This option is not available when a logarithmic axis is used.
- **Static Min:** Sets a fixed minimum value for the axis.
- **Static Max:** Sets a fixed maximum value for the axis. The value may be entered as a calculated formula. Click  $fx$  to open the **Edit Expression** dialog.
- **Static Step:** Sets a fixed interval for tick marks on the axis. If this setting results in more than 100 tick marks, the value used will be modified. The value may be entered as a calculated formula. Click  $fx$  to open the **Edit Expression** dialog.
- **Backcast:** By entering an integer in the edit field, you force the x-axis to be extended to the left of the actual data points plotted. This is useful when using trend lines. The backcast line will be dotted. The value may be entered as a calculated formula. Click  $fx$  to open the **Edit Expression** dialog.
- **Forecast:** By entering an integer in the edit field, you force the x-axis to be extended to the right of the actual data points plotted. This is useful when using trendlines. The forecast line will be dotted. The value may be entered as a calculated formula. Click  $fx$  to open the **Edit Expression** dialog.

## Expressions

To add an expression click . Choose expression in the list. The  icon moves the items in the list.

The  icon removes items from the list. Click on each dimension and make additional settings by clicking on the **More...** button.

## Expression

- **Enable:** Marking this check box will enable the selected expression. If the box is not marked, the expression will not be used at all.
- **Conditional:** Marking this check box hides or shows the expression dynamically, depending on the value of a condition expression entered, by clicking the *fx* button in the edit box below.
- **Label:** The label of the expression. Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Expression:** Displays the currently selected expression. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Comment:** Enter a comment to describe the purpose and function of the expression. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Invisible:** Hides the expression.
- **Show in Percent (Relative):** The chart shows the result in percent instead of absolute numbers.
- **Accumulate Expression:**

Check this box to accumulate expressions. Click  to open the popup.

- **Accumulation Popup:** Select one of the options to decide whether the values in the sheet object should be accumulated or not.
  - **Accumulate:** In an accumulated chart, each y-value is added to the y-value of the following x-value.
  - **No Accumulation:** The y-values of the selected chart expression will not be accumulated.
  - **Full Accumulation:** Each y-value accumulating all previous y-values of the expression. Full accumulation does not work if the chart trellis is enabled.
  - **Accumulation Steps:** Enter a number in the box or drag the slider to set the number of y-values in the expression to be accumulated.
- **Use Trendlines:**

Check this box to use trendlines. Click  to open the popup.

**Trendline Popup:** Choose one of the following Trendline options:

- **Average:** The average is plotted as a straight line.
- **Linear:** A linear regression line is plotted.
- **Polynomial of 2nd degree:** A polynomial trend line of the second degree is plotted.
- **Polynomial of 3rd degree:** A polynomial trend line of the third degree is plotted.
- **Polynomial of 4th degree:** A polynomial trend line of the fourth degree is plotted.
- **Exponential:** An exponential trend line is plotted.

For each option, it is possible to check the **Show Equation** box and the **Show R<sup>2</sup>** box.

- **Show Equation:** If this check box is marked for a specific expression, the expression's trend lines will be complemented by the trend line equation expressed as text in the chart.

- **Show R<sup>2</sup>**: If this check box is marked for a specific expression, the expression's trend lines will be complemented by the coefficient of determination expressed as text in the chart.

- **Show in Legend**: When several expressions are used, this option displays a legend showing the expressions and their corresponding colors next to the chart.

- **Statistical Distributions:**

Check this box to use statistical distribution. Click  to open the popup.

- **Statistical Distributions Popup**: Enable the checkboxes **Error Above**, **Error Below**, and **Error Symmetric** to utilize one or two expressions following the selected expression as auxiliary expressions for bars plotted on top on the main expression's data points.
  - If **Error Symmetric** is selected, then only one auxiliary expression will be used and plotted symmetrically around the data point.
  - If **Error Above** or **Error Below** is selected, then two auxiliary expressions will be used and plotted above and below the data point respectively.
  - The error bar expressions should return positive numbers.
  - The auxiliary expressions utilized for error bars are preceded by the icons (error symmetric), (error above) or (error below) in the Expressions list and cannot be utilized for anything else in the chart.
  - If there are no expressions already defined after the selected expression, new dummy auxiliary expressions will be created automatically.
- **Bar Border Settings Popup**: Specifies the width of the border line around bars in bar and combo charts.
- **Value Display Settings:**
  - **Show Values on Datapoints**: Mark this check box to display the result of the expression as text on top of the data points.
  - **Text as Popup**: Mark this check box to have the result of the expression shown in the popup balloon messages appearing when hovering over a data point in a chart in the layout. This option can be used with or without any of the other display options. It is thus possible to have an expression that does not appear in the chart itself, but only in hover popups.
  - **Text on Axis**: Plots the result of the expression at each x-axis value, the axis and the axis labels.
- **Attribute Expression Styles:**
  - **Background Color**: Define an attribute expression for calculating the basic plot color of the data point. The expression used should return a valid color representation (a number representing the Red, Green and Blue components as defined in Visual Basic) which is typically achieved by using one of the special chart color functions. If the result of the expression is not a valid color representation, black will be used.
  - **Bar Offset**: Define an attribute expression for calculating the bar offset.

- **Show Value:** Define an attribute expression for calculation whether the data point plot should be complemented with a “number on data point value”, even if **Values on Data Points** has not been selected for the main expression. If **Values on Data Points** is selected for the main expression the attribute expression will be disregarded.
- **Edit Expression** dialog: The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Number Format Tab:**
  - **Number Format Tab:** Each field has a default number format which can be set in the Document Properties: Number page. It is however possible to use a separate number format for an individual sheet object. This property page applies to the active object and contains the following controls for formatting values:
    - **Number Format:** Choose a number format from the alternatives below.
    - **Default:** Both numbers and text. Numbers are shown in original format.
    - **Number:** Shows numeric values with the number of digits set in the **Precision** field.
    - **Integer:** Shows numeric values as integers.
    - **Fixed to:** Shows numeric values as decimal values with the number of decimal digits set in the **Decimals** field.
    - **Money:** Shows values in the format set in the **Format Pattern** field. The default format is the Windows Currency setting.
    - **Date:** Shows values that can be interpreted as dates in the format set in the **Format Pattern** field.
    - **Time:** Shows values that can be interpreted as time in the format set in the **Format Pattern** field.
    - **Timestamp:** Shows values that can be interpreted as date + time in the format set in the **Format Pattern** field.
    - **Interval:** Shows time as sequential time increments (e.g. format = mm shows the value as the number of minutes since calendar start (1899:12:30:24:00)).
    - **Format Pattern:** The format code that further specifies the display format of the field. **ISO** sets the format to the ISO standard. Only valid for **Date**, **Time**, **Timestamp** and **Interval**. **Sys** sets the format to the system settings.
    - **Precision:** The number of digits that will be displayed.
    - **Decimals:** Sets the number of decimals included.
    - **Decimals Separator:** Sets the symbol for decimal separators.
    - **Thousand Separator:** Sets the symbol for thousand separators.
    - **In Percent:** Shows formatting in percentage instead of absolute numbers. The setting is only available for **Number**, **Integer** and **Fixed to**.
    - **Preview:** Shows a preview of the number format specified above.

#### Axis

- **Show Axis:** Check this box to show the axis.
- **Axis Width:** Enter the width of the axis and its tick marks, or drag the slider to the desired value.

- **Split Axis:** Check this box to split the y-axis into two parts, thus creating an impression of two charts sharing a common x-axis.
- **Position:** Choose **Left** or **Right** position.
- **Show Grid:** Check this box to show a grid in the chart originating from the tick marks of the x-axis. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Show Minor Grid:** Check this box to show minor lines in-between the grid lines. Only available if **Show Grid** is selected. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Log Scale:** If this box is checked, the scale will be logarithmic.
- **Force 0:** Fixes the lower edge of the chart to zero on the y-axis. This option is not available when a logarithmic axis is used.
- **Static Min:** Sets a fixed minimum value for the axis. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Max:** Sets a fixed maximum value for the axis. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Step:** Sets a fixed interval for tick marks on the axis. If this setting results in more than 100 tick marks, the value used will be modified. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Center:** Sets a fixed value on the axis which will be positioned in the center of the plot area. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

### Show Title

By default, the label of the first expression defined is set as chart title. Clear the check box if you do not wish to have a chart title. The title may be defined as a calculated formula for dynamic update. Click *fx* to open the **Edit Expression** dialog.

### More.../Less...

Click this button to expand/collapse the foldout that contains additional tabs. Depending on if the **Dimensions** or **Expressions** field is active, different tabs are displayed.

## Bar Chart Properties: Presentation

Some options may not be available for all objects.

### Look

Click  to open the popup.

- **Top Angle:** Defines the vertical angle of the 3D view. The value must be an integer between 0 and 30.
- **Side Angle:** Defines the side angle of the 3D view. The value must be an integer between 0 and 45.

### Orientation

Sets the orientation of the chart.

## Color Style

Defines the color style on all plot colors in the chart. Click  to open the popup.

- **Persistent Colors:** Locks the colors assigned to each data point even if selections reduce the total number of data points. In this mode color representation will never change for a given data point, but there is a risk of having two adjacent bars or slices with the same color for different data points.
- **Repeat Last Color:** Select this check box to assign the last (18th) color to field values loaded as number 18 and forward. If this check box is left unselected, the 19th value (according to the original load order) will get the first color, the 20th value the second color, etc.

## Show Legend

Displays the legend in the chart. Click  to open the popup.

- **Legend Style:** Sets the legend style.
- **Vertical:** Sets the vertical alignment of the legend.
- **Line Spacing:** Specifies the distance between items in the legend.
- **Reverse Order:** To reverse the sort order of the legend mark this check box.
- **Wrap Cell Text:** If this check box is marked, the text of the legend items will be wrapped in two or more lines.

## Stacked Bars

Checking this option displays the bars stacked instead of grouped.

## Bar Distance

Enter a number or drag the slider to set the distance between the bars in the cluster.

## Cluster Distance

Enter a number or drag the slider to set the distance between clusters in the chart.

## Background

Sets the background of the chart. The following options are available:

- **Color:** Click  to select a color.
- **Image:** Click  to change the image.
- **Dynamic Image:** Enter a calculated expression to show dynamic background images that change with the selection.

## Plot Area Background

Sets the background of the plot area. The following options are available:

- **Color:** The plot area will have a colored background. Click  to select a color.
- **Image:** The plot area will have an image background. Click  to change the image.
- **Dynamic Image:** Enter a calculated expression to show dynamic background images that change with the selection.

## Plot Area Style

This control can be used to change the appearance of the plot area background. The following options are available:

- **Frame:** A frame is drawn around the plot area.
- **Shadow:** This options gives a shadow effect on the plot area background.
- **Minimal:** The plot area background is removed.

## Background Transparency

Enter a value in the box or drag the slider to set transparency for the chart.

## More.../Less...

Click this button to expand/collapse the foldout that contains additional tabs.

## General

- **Reverse Direction:** When this check box is marked, the values shown in the chart will be reversed, i.e. if the 10 highest values are shown and the box is checked the chart will then show the 10 lowest values.
- **Max Values Shown:** In this box, specify an upper limit for how many data points to show values for in the chart. If no limit is specified, values will be shown for all data points, which may affect the readability of the chart.
- **Suppress Zero-Values:** If this check box is marked, all combinations of the dimension fields returning zero or null from all expressions will be disregarded in the calculation. This option is selected by default.
- **Zero on Bars:** This setting is only applicable when **Suppress Zero-Values** is deselected. If the check box is marked and **Values on Data Points** is selected, zero values will appear as text above the data points. In other cases zero values will be suppressed.
- **Suppress Missing:** If this check box is marked, all combinations of the dimension fields associated with only null values in all fields in all expressions will be disregarded in the calculation. This option is selected by default. Turning it off can be useful only in special cases, e.g. if null values is to be counted in a chart.
- **Synchronize Zero for Expression Axes:** Synchronizes the zero level of the two y-axes (left/right or top/bottom).
- **Use Full Symbol Set:** This alternative makes more symbol representations available (rings, triangles, etc.)
- **Allow Thin Bars:** For charts with a non-continuous x-axis, QlikView will only display as many data points as can be accommodated in the plot area available. Remaining data points are truncated

from the chart. By default bars will be drawn with a minimum width of four pixels, so that they are clearly distinguishable. Mark this check box to allow bar width down to one pixel.

- **Show All Bars:** For charts with a non-continuous x-axis, QlikView will only display as many data points as can be accommodated in the plot area available. Remaining data points are truncated from the chart. Mark this check box to force plotting of all bars. The bars will be compressed and some data points may become obscured by others.
- **Vertical Numbers:** Shows the values vertically.
- **Plot Numbers on Segments:** Marking this check box will plot values on data points inside the segments instead of on top of them.
- **Popup Labels:** By selecting this check box the values of the dimensions and expressions will appear as a pop-up balloon when hovering with the cursor over data point in the chart.
- **Highlight:** This option is not supported for AJAX/WebView.

### Chart Scrolling

Click  to open the popup.

- **Chart Scrolling Popup:** Enable this check box to show a scroll control in place of the X-axis, when the number of bars exceeds the defined number. The scroll bar can be used to scroll the selection of the X-axis values that are displayed.
- **Calculation Conditions:** The expression entered here sets a condition to be fulfilled for the chart to be calculated. If the condition is not fulfilled, the text 'Calculation condition unfulfilled' will be displayed in the chart. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.

### Styles

- **Legend:** To set the color of the legend click . To set the font color of the legend click . To set the font type click .
- **Chart Title Style:** To set the font color of the chart title click . To set the font type click .
- **Caption Font:** To set the caption font type click .
- **Active Caption:** To set the background color for the active caption click . To set the text color click .
- **Inactive Caption:** To set the background color for the inactive caption click . To set the text color click .
- **Use Border:** Mark this check box in order to use a border around the sheet object. Click the  to set the color of the border.
- **Border Width:** Specify a value or drag the slider to set the width of the border. The width is specified in pixels.

- **Rounded Corners:** Click  to open the **Rounded Corners** popup.

 **Rounded Corners** is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.

- **Rounded Corners Popup:** Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected. Also select **Squareness** by entering a value.
- **Scroll Bar Background:** To set the scroll bar background color click .
- **Scroll Bar Slider:** To set the scroll bar slider color click .
- **Scroll Bar Width:** Specify a value or drag the slider to set the width of the scroll bar. This control affects both the width and the relative size of the scroll bar symbols.
- **Trendline Width:** Specify the width of the trendline.
- **Error Bar:** To set the error bar slider color click .
- **Error Bar Width:** Specify the width of the error bar.
- **Error Bar Thickness:** Specify the thickness of the error bar.
- **Reference Lines:**
  - **Reference Lines:** Add a reference line by clicking .
  - **Show Label in Chart:** Displays the label next to the reference line.
  - **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
  - **X-Axis:** Select this option if the reference line should originate from the x-axis.
  - **Expression:** The value at which the reference line should be drawn. Enter an expression you wish to use as start point.
  - **Line Weight:** Specifies the weight of the reference line.
  - **Line Style:** Specifies the style of the reference line.
  - **Line Color:** Specifies the color of the reference line.
  - **Use Show Condition:** The reference line will be shown or hidden depending on a conditional expression which will be evaluated each time the chart is to be drawn. The reference line will only be hidden when the expression returns FALSE.
  - **Condition:** Enter the conditional expression. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
- **Text:**
  - **Text in Chart:** Click  to add text in the chart.
  - **Text:** The text added in **Text in Chart** are displayed here.
  - **Tilt Angle:** Specify an angle between 0 and 360 degrees for the text. The default is 0.

- **Horizontal Align:** Sets the horizontal alignment.
- **On Top:** The text currently selected in the list will be forced to the foreground when drawing the chart.
- **Text Style:**
  - To set the background color for the text click .
  - To set the font color click . To set the font type click .
- **Size Position:** Sets the position and size of the text on the object.

## Bar Chart Properties: Caption

### Caption

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.  
The value may be entered as a calculated formula.

Click  to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

### More.../Less...

The following icons in captions are available:

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!

- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Maximize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.
- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.  
Click  to open the popup.
- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Bar Chart Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.

- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.27 Line Chart - AJAX/Webview

Line charts present data as lines between value points, as value points only or as both lines and value points. Line charts are useful when you want to show changes or trends.

### Line Chart: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

Menu commands

| Command       | Details                                                         |
|---------------|-----------------------------------------------------------------|
| Properties... | Opens the <b>Properties</b> dialog for the active sheet object. |
| Notes         | Allows creating and sharing notes about the current object.     |

| Command              | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Detach               | The chart title is appended with the text "(Detached)" and the chart is no longer updated with selections made in the document (though selections may actually still be made from the chart). The command is available only if the chart is attached. By making a copy of a chart and detaching it, you may make direct comparisons between the copy and the original.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Attach               | Attaches a detached chart. The chart becomes dynamically linked to the data. The command is available only if the chart is detached.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Set Reference        | This option sets a chart reference, such as a fixed plot of the chart with the current selections. When further selections are made in the document the reference plot remains, dimmed in the background. Chart axes will be adjusted to always include the maximum of the background data set and the current data set. The current data set is always plotted on top of the reference plot. Some portions of the reference plot may be obscured by the current data set plot. The display of reference chart plots is only possible in some chart types, such as bar charts, line charts, combo charts, radar charts, scatter charts, grid charts and gauge charts with needles. It is not possible to set a reference for a chart that contains a drill-down or a cyclic group. The reference will be lost when closing the document or when reloading data. The maximum number of objects that can be included when using the <b>Set Reference</b> option is 500. |
| Clear Reference      | This command is replaced with the <b>Set Reference</b> command when a reference is set. By choosing it the previously set reference will be cleared and the chart will revert to normal plot mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Clear All Selections | Clears all the current selections in the active sheet object. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Copy                 | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Print...             | Opens the selected sheet object(s) in tabular format in another browser window.<br><br>Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Send to Excel        | Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Export...            | Opens the <b>Save as</b> dialog where path, file name and (table) file type for the exported data content can be specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Command     | Details                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fast Change | Makes it possible to change the current chart into another chart type. Clicking on the  icon in the object caption (if shown) produces the same result. Only available if <b>Fast Type Change in Chart</b> has been enabled on the <b>Caption</b> tab of the <b>Properties</b> dialog.               |
| Minimize    | Iconizes the object. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if minimizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                   |
| Restore     | Restores a minimized or maximized object to its previous size and location. Double-clicking the icon of a minimized object or clicking the  icon in the object caption (if shown) of a maximized object produces the same result. This command is available only for minimized or maximized objects. |
| Maximize    | Enlarges the object to fill the sheet. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if maximizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                 |
| Remove      | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                                                                           |

## Line Chart Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

### Dimensions

Choose dimensions in the drop-down list. To add a dimension, click . Select a dimension in the drop-down. Use the  icon to move items in the list. The  icon removes items from the list. For more settings, click the **More...** button.

### Dimension

This section describes the elements in **Dimension**.

- **Enable Conditional:** Marking this check box hides or shows the dimension dynamically, depending on the value of a condition expression entered, by clicking the  button in the edit box below.
- **Dimension:** Displays the currently selected dimension.
- **Show Label:** Mark this check box to show a dimension label (the field name) on the x-axis.
- **Suppress Null Values:** If this check box is marked, the field selected as **Dimension** above will not be displayed in the chart if its value is NULL.
- **Show All Values:** Mark this check box to show all the dimension field values in the chart, including logically excluded values.
- **Show Axis Labels:** Mark this check box to show legend (names of field values) on the x-axis for the selected dimension field.

- **Limit Axis Label Characters:** Mark this check box to limit the length of the dimension value strings to be shown on axes and in the chart legend. Specify the number of characters in the input field, or drag the slider to the desired value. Truncated values will be followed by ... in the chart. This option can be used independently to the other options in this group.
- **Trellis Setting First Dimension:** Marking this check box will enable the trellis chart, where an array of charts that are based on the chart's first dimension are displayed.
- **Fixed Number of Columns:** Enter the number of columns you want the trellis chart to display. Specify the number of columns in the input field, or drag the slider to the desired value.
- **Fixed Number of Rows:** Enter the number of rows you want the trellis chart to display. Specify the number of rows in the input field, or drag the slider to the desired value.
- **Second Dimension:** Enables the second dimension in the trellis chart. If a secondary dimension is used, the first dimension values will be displayed as columns in the trellis matrix, whereas the secondary dimension values will be displayed as rows in the trellis matrix.

## Sort

This section describes elements in **Sort**.

- Sets the sort order of the values in the sheet object. Some sort options may not be available for all sheet objects.  
If more than one sort order is specified, the sort order will be state, expression, frequency, numeric, text, load order. **State** refers to the logical state (selected, optional, or excluded).
- **Primary Sort: Y-Value:** Sets whether the dimension values should be sorted according to the numeric value of the y-axis. This option is not available for calculated dimensions. **Frequency:** Sorts the field values by frequency (number of concurrences in the table). **Numeric Value:** Sorts the field values by their numeric values. **Text:** Sorts the field values in alphabetical order. **Load Order:** Sorts the field values by the initial load order.
- **Secondary Sort: Frequency:** Sorts the field values by frequency (number of concurrences in the table).  
**Numeric Value:** Sorts the field values by their numeric values.  
**Text:** Sorts the field values in alphabetical order.  
**Load Order:** Sorts the field values by the initial load order.
- **Sort by Expression:** Sorts the field values according to the expression entered. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Keep Selected on Top:** Enable this to keep the selected values on top.

## Limits

This section describes elements in **Limits**.

- **Restrict which values are displayed using the first expression:** These properties are used to determine how many dimension values are displayed in the chart, according to settings made below.
- **Show only:**

- Select this option if you want to show the **First**, **Largest** or **Smallest** x number of values. If this option is set to 5, there will be five values displayed. If the dimension has **Show Others** enabled, the Others segment will take up one of the five display slots.
  - The **First** option will return the rows based on the options selected on the **Sort** tab of the property dialog. If the chart is a Straight Table, the rows will be returned based on the primary sort at the time. In other words, a user can change the values display by double-clicking on any column header and making that column the primary sort.
  - The **Largest** option returns the rows in descending order based on the first expression in the chart. When used in a Straight Table, the dimension values shown will remain consistent while interactively sorting the expressions. The dimensions values will (may) change when the order of the expressions is changed.
  - The **Smallest** option returns the rows in ascending order based on the first expression in the chart. When used in a Straight Table, the dimension values shown will remain consistent while interactively sorting the expressions. The dimensions values will (may) change when the order of the expressions is changed.
  - Enter the number of values to display.
  - The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
  - Select **Include Boundary Values** to include the dimension value that contains the comparison value.
- **Show only values that are:** Select this option to display all dimensions values that meet the specified condition for this option. Select to display values based on a percentage of the total, or on an exact amount. The **relative to the total** option enables a relative mode which is similar to the **Relative** option on the **Expressions** tab of the property dialog. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Show only values that accumulate to:** When this option is selected, all rows up to the current row are accumulated, and the result is compared to the value set in the option. The **relative to the total** option enables a relative mode which is similar to the **Relative** option on the **Expressions** tab of the property dialog, and compares the accumulated values (based on first, largest or smallest values) to the overall total. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Show Others:** Enabling this option will produce an **Others** segment in the chart. All dimension values that do not meet the comparison criteria for the display restrictions will be grouped into the **Others** segment. If there are dimensions after the selected dimension, **Collapse Inner Dimensions** will control whether individual values for the subsequent / inner dimensions display on the chart. In the **Label** field, enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text.

The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

If there are dimensions after the selected dimension, **Collapse Inner Dimensions** will control whether individual values for the subsequent / inner dimensions display on the chart.
- **Show Total:** The chart will display a total for the selected dimension when this option is enabled. This total behaves differently than the expression total, which is still configured on the **Expressions**

tab of the property dialog. **Label:** Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

- **Use Global Grouping Mode:**
- The option only applies to inner dimensions. When this option is enabled the restrictions will be calculated on the selected dimension only. All previous dimensions will be ignored. If this is disabled, the restrictions are calculated based on all preceding dimensions.

## Axis

This section describes elements in **Axis**.

- **Show Axis:** Check this box to show the axis.
- **Axis Width:** Enter the width of the axis and its tick marks, or drag the slider to the desired value.
- **Major Label:** Select **Horizontal**, **Vertical** or **Tilted** display of the major labels.
- **Minor Label:** Select **Horizontal**, **Vertical** or **Tilted** display of the minor labels.
- **Show Grid:** Check this box to show a grid in the chart originating from the tick marks of the x-axis. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Show Minor Grid:** Check this box to show minor lines in-between the grid lines. Only available if **Show Grid** is selected. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Stagger Labels:** Select this option to stagger x-axis labels when they become too many to show side by side.
- **Reverse Stagger:** X-axis labels are normally staggered bottom-up from left to right. When marking this check box, the stagger will be reversed to top-down.
- **Continuous X:** Sets the x-axis to be continuous, i.e. it will be interpreted numerically and shown with numerically correct intervals.
- **Force 0:** Fixes the lower edge of the chart to zero on the y-axis. This option is not available when a logarithmic axis is used.
- **Static Min:** Sets a fixed minimum value for the axis. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Max:** Sets a fixed maximum value for the axis. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Step:** Sets a fixed interval for tick marks on the axis. If this setting results in more than 100 tick marks, the value used will be modified. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Backcast:** By entering an integer in the edit field, you force the x-axis to be extended to the left of the actual data points plotted. This is useful when using trend lines. The backcast line will be dotted. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Forecast:** By entering an integer in the edit field, you force the x-axis to be extended to the right of the actual data points plotted. This is useful when using trendlines. The forecast line will be dotted. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

## Expressions

Choose expressions in the drop-down list. To add an expression, click . Select an expression from the drop-down. Use the  icon to move items in the list. The  icon removes items from the list. For more information click the **More...** button.

### Expression

This section describes the elements in **Expression**.

- **Enable:** Marking this check box will enable the selected expression. If the box is not marked, the expression will not be used at all.
- **Conditional:** Marking this check box hides or shows the expression dynamically, depending on the value of a condition expression entered, by clicking the *fx* button in the edit box below.
- **Label:** The label of the expression. Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Expression:** Displays the currently selected expression.
- **Comment:** Enter a comment to describe the purpose and function of the expression. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Invisible:** Hides the expression.
- **Show in Percent (Relative):** The chart shows the result in percent instead of absolute numbers.
- **Accumulate Expression:**

Check this box to accumulate expressions. Click  to open the popup.

- **Accumulation Popup:** Select one of the options to decide whether the values in the sheet object should be accumulated or not.
  - **Accumulate:** In an accumulated chart, each y-value is added to the y-value of the following x-value.
  - **No Accumulation:** The y-values of the selected chart expression will not be accumulated.
  - **Full Accumulation:** Each y-value accumulating all previous y-values of the expression. Full accumulation does not work if the chart trellis is enabled.
  - **Accumulation Steps:** Enter a number in the box or drag the slider to set the number of y-values in the expression to be accumulated.
- **Use Trendlines:**

Check this box to use trendlines. Click  to open the popup.

**Trendline Popup:** Choose one of the following Trendline options:

- **Average:** The average is plotted as a straight line.
- **Linear:** A linear regression line is plotted.

- **Polynomial of 2nd degree:** A polynomial trend line of the second degree is plotted.
  - **Polynomial of 3rd degree:** A polynomial trend line of the third degree is plotted.
  - **Polynomial of 4th degree:** A polynomial trend line of the fourth degree is plotted.
  - **Exponential:** An exponential trend line is plotted.  
For each option, it is possible to check the **Show Equation** box and the **Show R<sup>2</sup>** box.
    - **Show Equation:** If this check box is marked for a specific expression, the expression's trend lines will be complemented by the trend line equation expressed as text in the chart.
    - **Show R<sup>2</sup>:** If this check box is marked for a specific expression, the expression's trend lines will be complemented by the coefficient of determination expressed as text in the chart.
- 
- **Show in Legend:** When several expressions are used, this option displays a legend showing the expressions and their corresponding colors next to the chart.
  - **Line Symbol Settings:** Check this box to make layout settings for bars, lines and symbols. Click  to open the popup.
    - **Line Symbol Settings Popup:**
      - **Line:** Make settings for the layout of lines.
      - **Symbol:** Make settings for the layout of used symbols.
  - **Value Display Settings:**
    - **Show Values on Datapoints:** Mark this check box to display the result of the expression as text on top of the data points.
    - **Text as Popup:** Mark this check box to have the result of the expression shown in the popup balloon messages appearing when hovering over a data point in a chart in the layout. This option can be used with or without any of the other display options. It is thus possible to have an expression that does not appear in the chart itself, but only in hover popups.
    - **Text on Axis:** Plots the result of the expression at each x-axis value, the axis and the axis labels.
  - **Attribute Expression Styles:**
    - **Background Color:** Define an attribute expression for calculating the basic plot color of the data point. The expression used should return a valid color representation (a number representing the Red, Green and Blue components as defined in Visual Basic) which is typically achieved by using one of the special chart color functions. If the result of the expression is not a valid color representation, black will be used.
    - **Line Style:** Click on **Line Style** in order to enter an attribute expression for calculating the line style for the line or line segment associated with the data point. This type of attribute expression only has effect on line, combo and radar charts.

- The relative width of the line can be controlled by including a tag <Wn> where n is a multiplying factor to be applied on the default line width of the chart. The number n must be a real number between 0.5 and 8. Example: <W2.5>. The style of the line can be controlled by including a tag <Sn> where n is an integer between 1 and 4 indicating the style to be used (1=continuous, 2= dashed, 3=dotted, 4=dashed/dotted). Example: <S3>. The <Wn> and <Sn> tags can be freely combined, but only the first occurrence of each counts. The tags must be enclosed by single quotations.
- **Show Value:**
  - Define an attribute expression for calculation whether the data point plot should be complemented with a “number on data point value“, even if **Values on Data Points** has not been selected for the main expression. If **Values on Data Points** is selected for the main expression the attribute expression will be disregarded.
    - **Number Format Tab:** Each field has a default number format which can be set in the Document Properties: Number page. It is however possible to use a separate number format for an individual sheet object. This property page applies to the active object and contains the following controls for formatting values:
      - **Number Format:** Choose a number format from the alternatives below.
      - **Default:** Both numbers and text. Numbers are shown in original format.
      - **Number:** Shows numeric values with the number of digits set in the **Precision** field.
      - **Integer:** Shows numeric values as integers.
      - **Fixed to:** Shows numeric values as decimal values with the number of decimal digits set in the **Decimals** field.
      - **Money:** Shows values in the format set in the **Format Pattern** field. The default format is the Windows Currency setting.
      - **Date:** Shows values that can be interpreted as dates in the format set in the **Format Pattern** field.
      - **Time:** Shows values that can be interpreted as time in the format set in the **Format Pattern** field.
      - **Timestamp:** Shows values that can be interpreted as date + time in the format set in the **Format Pattern** field.
      - **Interval:** Shows time as sequential time increments (e.g. format = mm shows the value as the number of minutes since calendar start (1899:12:30:24:00)).
      - **Format Pattern:** The format code that further specifies the display format of the field. **ISO** sets the format to the ISO standard. Only valid for **Date**, **Time**, **Timestamp** and **Interval**. **Sys** sets the format to the system settings.
      - **Precision:** The number of digits that will be displayed.
      - **Decimals:** Sets the number of decimals included.
      - **Decimals Separator:** Sets the symbol for decimal separators.

- **Thousand Separator:** Sets the symbol for thousand separators.
- **In Percent:** Shows formatting in percentage instead of absolute numbers. The setting is only available for **Number**, **Integer** and **Fixed to**.
- **Preview:** Shows a preview of the number format specified above.

## Axis

This section describes elements in **Axis**.

- **Show Axis:** Check this box to show the axis.
- **Axis Width:** Enter the width of the axis and its tick marks, or drag the slider to the desired value.
- **Split Axis:** Check this box to split the y-axis into two parts, thus creating an impression of two charts sharing a common x-axis.
- **Position:** Choose **Left** or **Right** position.
- **Show Grid:** Check this box to show a grid in the chart originating from the tick marks of the x-axis. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Show Minor Grid:** Check this box to show minor lines in-between the grid lines. Only available if **Show Grid** is selected. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Log Scale:** If this box is checked, the scale will be logarithmic.
- **Force 0:** Fixes the lower edge of the chart to zero on the y-axis. This option is not available when a logarithmic axis is used.
- **Static Min:** Sets a fixed minimum value for the axis. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Max:** Sets a fixed maximum value for the axis. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Step:** Sets a fixed interval for tick marks on the axis. If this setting results in more than 100 tick marks, the value used will be modified. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Center:** Sets a fixed value on the axis which will be positioned in the center of the plot area. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

## Show Title

By default, the label of the first expression defined is set as chart title. Clear the check box if you do not wish to have a chart title. The title may be defined as a calculated formula for dynamic update. Click *fx* to open the **Edit Expression** dialog.

## More.../Less...

Click this button to expand/collapse the foldout that contains additional tabs. Depending on if the **Dimensions** or **Expressions** field is active, different tabs are displayed.

## Line Chart Properties: Presentation

This section describes **Presentation** properties.

### Presentation options

Some options may not be available for all objects.

#### Look

Select one of the available looks in the drop-down.

Click  to open the popup.

- **Bar 3D Look Settings Popup:**
  - **Top Angle:** Defines the vertical angle of the 3D view. The value must be an integer between 5 and 45.
  - **Side Angle:** Defines the side angle of the 3D view. The value must be an integer between 5 and 45.

#### Orientation

Sets the orientation of the chart.

#### Color Style

Defines the color style on all plot colors in the chart. Click  to open the popup.

- **Color Properties Popup:**
  - **Persistent Colors:** Locks the colors assigned to each data point even if selections reduce the total number of data points. In this mode color representation will never change for a given data point, but there is a risk of having two adjacent bars or slices with the same color for different data points.
  - **Repeat Last Color:** Select this check box to assign the last (18th) color to field values loaded as number 18 and forward. If this check box is left unselected, the 19th value (according to the original load order) will get the first color, the 20th value the second color, etc.

#### Show Legend

Displays the legend in the chart. Click  to open the popup.

- **Legend Settings Popup:**
  - **Legend Style:** Sets the legend style.
  - **Vertical Placement:** Sets the vertical alignment of the legend.
  - **Line Spacing:** Specifies the distance between items in the legend.
  - **Reverse Order:** To reverse the sort order of the legend mark this check box.
  - **Wrap Cell Text:** If this check box is marked, the text of the legend items will be wrapped in two or more lines.

#### Stacked Bars

Checking this option displays the bars stacked instead of grouped.

#### Bar Distance

Enter a number or drag the slider to set the distance between the bars in the cluster.

### Cluster Distance

Enter a number or drag the slider to set the distance between clusters in the chart.

### Background

Sets the background of the chart. The following options are available:

- **Color:** Click  to select a color.
- **Image:** Click  to change the image.
- **Dynamic Image:** Enter a calculated expression to show dynamic background images that change with the selection.

### Plot Area Background

Sets the background of the plot area. The following options are available:

- **Color:** The plot area will have a colored background. Click  to select a color.
- **Image:** The plot area will have an image background. Click  to change the image.
- **Dynamic Image:** Enter a calculated expression to show dynamic background images that change with the selection.

### Plot Area Style

This control can be used to change the appearance of the plot area background. The following options are available:

- **Frame:** A frame is drawn around the plot area.
- **Shadow:** This options gives a shadow effect on the plot area background.
- **Minimal:** The plot area background is removed.

### Background Transparency

Enter a value in the box or drag the slider to set transparency for the chart.

### More.../Less...

- **General:**
  - **Reverse Direction:** When this check box is marked, the values shown in the chart will be reversed, i.e. if the 10 highest values are shown and the box is checked the chart will then show the 10 lowest values.
  - **Max Values Shown:** In this box, specify an upper limit for how many data points to show values for in the chart. If no limit is specified, values will be shown for all data points, which may affect the readability of the chart.
  - **Suppress Zero-Values:** If this check box is marked, all combinations of the dimension fields returning zero or null from all expressions will be disregarded in the calculation. This option is selected by default.

- **Suppress Missing:** If this check box is marked, all combinations of the dimension fields associated with only null values in all fields in all expressions will be disregarded in the calculation. This option is selected by default. Turning it off can be useful only in special cases, e.g. if null values is to be counted in a chart.
- **Synchronize Zero for Expression Axes:** Synchronizes the zero level of the two y-axes (left/right or top/bottom).
- **Use Full Symbol Set:** This alternative makes more symbol representations available (rings, triangles, etc.)
- **Semi-transparent:** Check this box to make filled lines be drawn semi-transparent.
- **Vertical Numbers:** Shows the values vertically.
- **Plot Numbers on Segments:** Marking this check box will plot values on data points inside the segments instead of on top of them.
- **Popup Labels:** By selecting this check box the values of the dimension(s) and expression(s) will appear as a pop-up balloon when hovering with the cursor over data point in the chart.
- **Highlight:** This option is not supported for AJAX/WebView.
- **Chart Scrolling:** Click  to open the popup.
  - **Chart Scrolling Popup:** Enable this check box to show a scroll control in place of the X-axis, when the number of bars exceeds the defined number. The scroll bar can be used to scroll the selection of the X-axis values that are displayed.
- **Calculation Conditions:** The expression entered here sets a condition to be fulfilled for the chart to be calculated. If the condition is not fulfilled, the text 'Calculation condition unfulfilled' will be displayed in the chart. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
- **Styles:**
  - **Legend:** To set the color of the legend click . To set the font color of the legend click . To set the font type click .
  - **Chart Title Style:** To set the font color of the chart title click . To set the font type click .
  - **Caption Font:** To set the caption font type click .
  - **Active Caption:** To set the background color for the active caption click . To set the text color click .
  - **Inactive Caption:** To set the background color for the inactive caption click . To set the text color click .
  - **Use Border:** Mark this check box in order to use a border around the sheet object. Click the  to set the color of the border.

- **Border Width:** Specify a value or drag the slider to set the width of the border. The width is specified in pixels.
- **Rounded Corners:** Click  to open the **Rounded Corners** popup.

***Rounded Corners** is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.*

- **Rounded Corners Popup:** Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected. Select **Squareness** by entering a value.
- **Scroll Bar Background:** To set the scroll bar background color click .
- **Scroll Bar Slider:** To set the scroll bar slider color click .
- **Scroll Bar Width:** Specify a value or drag the slider to set the width of the scroll bar. This control affects both the width and the relative size of the scroll bar symbols.
- **Trendline Width:** Specify the width of the trendline.
  - **Reference Lines:**
    - **Reference Lines:** Add a reference line by clicking .
    - **Show Label in Chart:** Displays the label next to the reference line.
    - **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
    - **X-Axis:** Select this option if the reference line should originate from the x-axis.
    - **Expression:** The value at which the reference line should be drawn. Enter an expression you wish to use as start point.
    - **Line Weight:** Specifies the weight of the reference line.
    - **Line Style:** Specifies the style of the reference line.
    - **Line Color:** Specifies the color of the reference line.
    - **Use Show Condition:** The reference line will be shown or hidden depending on a conditional expression which will be evaluated each time the chart is to be drawn. The reference line will only be hidden when the expression returns FALSE.
    - **Condition:** Enter the conditional expression. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
  - **Text:**
    - **Text in Chart:** Click  to add text in the chart.
    - **Text:** The text added in **Text in Chart** are displayed here.
    - **Tilt Angle:** Specify an angle between 0 and 360 degrees for the text. The default is 0.

- **Horizontal Align:** Sets the horizontal alignment.
- **On Top:** The text currently selected in the list will be forced to the foreground when drawing the chart.
- **Text Style:**
  - To set the background color for the text click .
  - To set the font color click . To set the font type click .
- **Size Position:** Sets the position and size of the text on the object.

## Line Chart Properties: Caption

This section describes **Caption** properties.

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.

The value may be entered as a calculated formula.

Click  to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

## Icons in Caption

This section describes the elements in the **More.../Less...** property.

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!

- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Maximize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.
- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.  
Click  to open the popup.
- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Line Chart Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.

- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.28 Combo Chart - AJAX/WebView

The combo chart allows you to combine the features of the bar chart with those of the line chart: you can show the values of one expression as bars while displaying those of a second expression as lines or symbols.

### Combo Chart: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

Menu commands

| Command       | Details                                                         |
|---------------|-----------------------------------------------------------------|
| Properties... | Opens the <b>Properties</b> dialog for the active sheet object. |
| Notes         | Allows creating and sharing notes about the current object.     |

| Command              | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Detach               | The chart title is appended with the text "(Detached)" and the chart is no longer updated with selections made in the document (though selections may actually still be made from the chart). The command is available only if the chart is attached. By making a copy of a chart and detaching it, you may make direct comparisons between the copy and the original.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Attach               | Attaches a detached chart. The chart becomes dynamically linked to the data. The command is available only if the chart is detached.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Set Reference        | This option sets a chart reference, such as a fixed plot of the chart with the current selections. When further selections are made in the document the reference plot remains, dimmed in the background. Chart axes will be adjusted to always include the maximum of the background data set and the current data set. The current data set is always plotted on top of the reference plot. Some portions of the reference plot may be obscured by the current data set plot. The display of reference chart plots is only possible in some chart types, such as bar charts, line charts, combo charts, radar charts, scatter charts, grid charts and gauge charts with needles. It is not possible to set a reference for a chart that contains a drill-down or a cyclic group. The reference will be lost when closing the document or when reloading data. The maximum number of objects that can be included when using the <b>Set Reference</b> option is 500. |
| Clear Reference      | This command is replaced with the <b>Set Reference</b> command when a reference is set. By choosing it the previously set reference will be cleared and the chart will revert to normal plot mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Clear All Selections | Clears all the current selections in the active sheet object. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Copy                 | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Print...             | Opens the selected sheet object(s) in tabular format in another browser window.<br><br>Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Send to Excel        | Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Export...            | Opens the <b>Save as</b> dialog where path, file name and (table) file type for the exported data content can be specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Command     | Details                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fast Change | Makes it possible to change the current chart into another chart type. Clicking on the  icon in the object caption (if shown) produces the same result. Only available if <b>Fast Type Change in Chart</b> has been enabled on the <b>Caption</b> tab of the <b>Properties</b> dialog.                 |
| Minimize    | Iconizes the object. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if minimizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                     |
| Restore     | Restores a minimized or maximized object to its previous size and location. Double-clicking the icon of a minimized object or clicking the  icon in the object caption (if shown) of a maximized object produces the same result. This command is available only for minimized or maximized objects. |
| Maximize    | Enlarges the object to fill the sheet. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if maximizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                  |
| Remove      | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                                                                             |

## Combo Chart Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

## Dimensions

Choose dimensions in the drop-down list. To add a dimension, click . Select a dimension in the drop-down. Use the  icon to move items in the list. The  icon removes items from the list. For more settings, click the **More...** button.

## Dimension

- **Enable Conditional:** Marking this check box hides or shows the dimension dynamically, depending on the value of a condition expression entered, by clicking the  button in the edit box below.
- **Dimension:** Displays the currently selected dimension.
- **Show Label:** Mark this check box to show a dimension label (the field name) on the x-axis.
- **Suppress Null Values:** If this check box is marked, the field selected as **Dimension** above will not be displayed in the chart if its value is NULL.
- **Show All Values:** Mark this check box to show all the dimension field values in the chart, including logically excluded values.
- **Show Axis Labels:** Mark this check box to show legend (names of field values) on the x-axis for the selected dimension field.

- **Limit Axis Label Characters:** Mark this check box to limit the length of the dimension value strings to be shown on axes and in the chart legend. Specify the number of characters in the input field, or drag the slider to the desired value. Truncated values will be followed by ... in the chart. This option can be used independently to the other options in this group.
- **Trellis Setting First Dimension:** Marking this check box will enable the trellis chart, where an array of charts that are based on the chart's first dimension are displayed.
- **Fixed Number of Columns:** Enter the number of columns you want the trellis chart to display. Specify the number of columns in the input field, or drag the slider to the desired value.
- **Fixed Number of Rows:** Enter the number of rows you want the trellis chart to display. Specify the number of rows in the input field, or drag the slider to the desired value.
- **Second Dimension:** Enables the second dimension in the trellis chart. If a secondary dimension is used, the first dimension values will be displayed as columns in the trellis matrix, whereas the secondary dimension values will be displayed as rows in the trellis matrix.

## Sort

Sets the sort order of the values in the sheet object. Some sort options may not be available for all sheet objects.

If more than one sort order is specified, the sort order will be state, expression, frequency, numeric, text, load order. **State** refers to the logical state (selected, optional, or excluded).

- **Primary Sort: Y-Value:** Sets whether the dimension values should be sorted according to the numeric value of the y-axis. This option is not available for calculated dimensions. **Frequency:** Sorts the field values by frequency (number of concurrences in the table). **Numeric Value:** Sorts the field values by their numeric values. **Text:** Sorts the field values in alphabetical order. **Load Order:** Sorts the field values by the initial load order.
- **Secondary Sort: Frequency:** Sorts the field values by frequency (number of concurrences in the table).  
**Numeric Value:** Sorts the field values by their numeric values.  
**Text:** Sorts the field values in alphabetical order.  
**Load Order:** Sorts the field values by the initial load order.
- **Sort by Expression:** Sorts the field values according to the expression entered. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Keep Selected on Top:** Enable this to keep the selected values on top.

## Limits

- **Restrict which values are displayed using the first expression:** These properties are used to determine how many dimension values are displayed in the chart, according to settings made below.
- **Show only:** Select this option if you want to show the **First**, **Largest** or **Smallest** x number of values. If this option is set to 5, there will be five values displayed. If the dimension has **Show Others** enabled, the Others segment will take up one of the five display slots. The **First** option will return the rows based on the options selected on the **Sort** tab of the property dialog. If the chart is a Straight Table, the rows will be returned based on the primary sort at the time. In other words, a user can change the values display by double-clicking on any column header and making that column the

primary sort. The **Largest** option returns the rows in descending order based on the first expression in the chart. When used in a Straight Table, the dimension values shown will remain consistent while interactively sorting the expressions. The dimensions values will (may) change when the order of the expressions is changed. The **Smallest** option returns the rows in ascending order based on the first expression in the chart. When used in a Straight Table, the dimension values shown will remain consistent while interactively sorting the expressions. The dimensions values will (may) change when the order of the expressions is changed. Enter the number of values to display. The value may be entered as a calculated formula. Click  $fx$  to open the **Edit Expression** dialog. Select **Include Boundary Values** to include the dimension value that contains the comparison value.

- **Show only values that are:** Select this option to display all dimensions values that meet the specified condition for this option. Select to display values based on a percentage of the total, or on an exact amount. The **relative to the total** option enables a relative mode which is similar to the **Relative** option on the **Expressions** tab of the property dialog. The value may be entered as a calculated formula. Click  $fx$  to open the **Edit Expression** dialog.
- **Show only values that accumulate to:** When this option is selected, all rows up to the current row are accumulated, and the result is compared to the value set in the option. The **relative to the total** option enables a relative mode which is similar to the **Relative** option on the **Expressions** tab of the property dialog, and compares the accumulated values (based on first, largest or smallest values) to the overall total. The value may be entered as a calculated formula. Click  $fx$  to open the **Edit Expression** dialog.
- **Show Others:** Enabling this option will produce an **Others** segment in the chart. All dimension values that do not meet the comparison criteria for the display restrictions will be grouped into the **Others** segment. If there are dimensions after the selected dimension, **Collapse Inner Dimensions** will control whether individual values for the subsequent / inner dimensions display on the chart. In the **Label** field, enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text.  
The value may be entered as a calculated formula. Click  $fx$  to open the **Edit Expression** dialog. If there are dimensions after the selected dimension, **Collapse Inner Dimensions** will control whether individual values for the subsequent / inner dimensions display on the chart.
- **Show Total:** The chart will display a total for the selected dimension when this option is enabled. This total behaves differently than the expression total, which is still configured on the **Expressions** tab of the property dialog. **Label:** Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text. The value may be entered as a calculated formula. Click  $fx$  to open the **Edit Expression** dialog.
- **Use Global Grouping Mode:** The option only applies to inner dimensions. When this option is enabled the restrictions will be calculated on the selected dimension only. All previous dimensions will be ignored. If this is disabled, the restrictions are calculated based on all preceding dimensions.

#### Axis

- **Show Axis:** Check this box to show the axis.
- **Axis Width:** Enter the width of the axis and its tick marks, or drag the slider to the desired value.
- **Major Label:** Select **Horizontal**, **Vertical** or **Tilted** display of the major labels.
- **Minor Label:** Select **Horizontal**, **Vertical** or **Tilted** display of the minor labels.

- **Show Grid:** Check this box to show a grid in the chart originating from the tick marks of the x-axis. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Show Minor Grid:** Check this box to show minor lines in-between the grid lines. Only available if **Show Grid** is selected. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Stagger Labels:** Select this option to stagger x-axis labels when they become too many to show side by side.
- **Reverse Stagger:** X-axis labels are normally staggered bottom-up from left to right. When marking this check box, the stagger will be reversed to top-down.
- **Continuous X:** Sets the x-axis to be continuous, i.e. it will be interpreted numerically and shown with numerically correct intervals.
- **Force 0:** Fixes the lower edge of the chart to zero 0 on the y-axis. This option is not available when a logarithmic axis is used.
- **Static Min:** Sets a fixed minimum value for the axis. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Max:** Sets a fixed maximum value for the axis. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Step:** Sets a fixed interval for tick marks on the axis. If this setting results in more than 100 tick marks, the value used will be modified. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Backcast:** By entering an integer in the edit field, you force the x-axis to be extended to the left of the actual data points plotted. This is useful when using trend lines. The backcast line will be dotted. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Forecast:** By entering an integer in the edit field, you force the x-axis to be extended to the right of the actual data points plotted. This is useful when using trendlines. The forecast line will be dotted. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

## Expressions

Choose expressions in the drop-down list. To add an expression, click . Select an expression from the drop-down. Use the  icon to move items in the list. The  icon removes items from the list. For more information click the **More...** button.

### Expression

- **Enable:** Marking this check box will enable the selected expression. If the box is not marked, the expression will not be used at all.
- **Conditional:** Marking this check box hides or shows the expression dynamically, depending on the value of a condition expression entered, by clicking the *fx* button in the edit box below.
- **Label:** The label of the expression. Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

- **Expression:** Displays the currently selected expression.
- **Comment:** Enter a comment to describe the purpose and function of the expression. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
- **Invisible:** Hides the expression.
- **Show in Percent (Relative):** The chart shows the result in percent instead of absolute numbers.
- **Accumulate Expression:**

Check this box to accumulate expressions. Click  to open the popup.

- **Accumulation Popup:** Select one of the options to decide whether the values in the sheet object should be accumulated or not.
  - **Accumulate:** In an accumulated chart, each y-value is added to the y-value of the following x-value.
  - **No Accumulation:** The y-values of the selected chart expression will not be accumulated.
  - **Full Accumulation:** Each y-value accumulating all previous y-values of the expression. Full accumulation does not work if the chart trellis is enabled.
  - **Accumulation Steps:** Enter a number in the box or drag the slider to set the number of y-values in the expression to be accumulated.
- **Use Trendlines:**

Check this box to use trendlines. Click  to open the popup.

**Trendline Popup:** Choose one of the following Trendline options:

- **Average:** The average is plotted as a straight line.
- **Linear:** A linear regression line is plotted.
- **Polynomial of 2nd degree:** A polynomial trend line of the second degree is plotted.
- **Polynomial of 3rd degree:** A polynomial trend line of the third degree is plotted.
- **Polynomial of 4th degree:** A polynomial trend line of the fourth degree is plotted.
- **Exponential:** An exponential trend line is plotted.

For each option, it is possible to check the **Show Equation** box and the **Show R<sup>2</sup>** box.

- **Show Equation:** If this check box is marked for a specific expression, the expression's trend lines will be complemented by the trend line equation expressed as text in the chart.
  - **Show R<sup>2</sup>:** If this check box is marked for a specific expression, the expression's trend lines will be complemented by the coefficient of determination expressed as text in the chart.
- 
- **Show in Legend:** When several expressions are used, this option displays a legend showing the expressions and their corresponding colors next to the chart.
  - **Statistical Distribution:**

Check this box to use statistical distribution. Click  to open the popup.

- **Statistical Distributions Popup:** Enable the checkboxes **Error Above**, **Error Below**, and **Error Symmetric** to utilize one or two expressions following the selected expression as auxiliary expressions for bars plotted on top on the main expression's data points.
  - If **Error Symmetric** is selected, then only one auxiliary expression will be used and plotted symmetrically around the data point.
  - If **Error Above** or **Error Below** is selected, then two auxiliary expressions will be used and plotted above and below the data point respectively.
  - The error bar expressions should return positive numbers.
  - The auxiliary expressions utilized for error bars are preceded by the icons (error symmetric), (error above) or (error below) in the Expressions list and cannot be utilized for anything else in the chart.
  - If there are no expressions already defined after the selected expression, new dummy auxiliary expressions will be created automatically.

• **Bar, Line, Symbol Settings:**

Check this box to make layout settings for bars, lines and symbols. Click  to open the popup.

Bar, Line, Symbol Settings Popup

**Bar**

Enter a value or drag the slider to specify the width of the border line around bars and combo charts.

**Line**

Make settings for the layout of lines.

**Symbol**

Make settings for the layout of used symbols.

• **Value Display Settings:**

- **Show Values on Datapoints:** Mark this check box to display the result of the expression as text on top of the data points.
- **Text as Popup:** Mark this check box to have the result of the expression shown in the popup balloon messages appearing when hovering over a data point in a chart in the layout. This option can be used with or without any of the other display options. It is thus possible to have an expression that does not appear in the chart itself, but only in hover popups.
- **Text on Axis:** Plots the result of the expression at each x-axis value, the axis and the axis labels.

• **Attribute Expression Styles:**

- **Background Color:** Define an attribute expression for calculating the basic plot color of the data point. The expression used should return a valid color representation (a number representing the Red, Green and Blue components as defined in Visual Basic) which is typically achieved by using one of the special chart color functions. If the result of the expression is not a valid color representation, black will be used.
- **Bar Offset:** Define an attribute expression for calculating the bar offset.
- **Line Style:** Define an attribute expression for calculating the line style.

- **Show Value:** Define an attribute expression for calculation whether the data point plot should be complemented with a “number on data point value”, even if **Values on Data Points** has not been selected for the main expression. If **Values on Data Points** is selected for the main expression the attribute expression will be disregarded.
- **Number Format Tab:** Each field has a default number format which can be set in the Document Properties: Number page. It is however possible to use a separate number format for an individual sheet object. This property page applies to the active object and contains the following controls for formatting values:
  - **Number Format:** Choose a number format from the alternatives below.
  - **Default:** Both numbers and text. Numbers are shown in original format.
  - **Number:** Shows numeric values with the number of digits set in the **Precision** field.
  - **Integer:** Shows numeric values as integers.
  - **Fixed to:** Shows numeric values as decimal values with the number of decimal digits set in the **Decimals** field.
  - **Money:** Shows values in the format set in the **Format Pattern** field. The default format is the Windows Currency setting.
  - **Date:** Shows values that can be interpreted as dates in the format set in the **Format Pattern** field.
  - **Time:** Shows values that can be interpreted as time in the format set in the **Format Pattern** field.
  - **Timestamp:** Shows values that can be interpreted as date + time in the format set in the **Format Pattern** field.
  - **Interval:** Shows time as sequential time increments (e.g. format = mm shows the value as the number of minutes since calendar start (1899:12:30:24:00)).
  - **Format Pattern:** The format code that further specifies the display format of the field. **ISO** sets the format to the ISO standard. Only valid for **Date**, **Time**, **Timestamp** and **Interval**. **Sys** sets the format to the system settings.
  - **Precision:** The number of digits that will be displayed.
  - **Decimals:** Sets the number of decimals included.
  - **Decimals Separator:** Sets the symbol for decimal separators.
  - **Thousand Separator:** Sets the symbol for thousand separators.
  - **In Percent:** Shows formatting in percentage instead of absolute numbers. The setting is only available for **Number**, **Integer** and **Fixed to**.
  - **Preview:** Shows a preview of the number format specified above.

### Axis

- **Show Axis:** Check this box to show the axis.
- **Axis Width:** Enter the width of the axis and its tick marks, or drag the slider to the desired value.
- **Split Axis:** Check this box to split the y-axis into two parts, thus creating an impression of two charts sharing a common x-axis.
- **Position:** Choose **Left** or **Right** position.

- **Show Grid:** Check this box to show a grid in the chart originating from the tick marks of the x-axis. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Show Minor Grid:** Check this box to show minor lines in-between the grid lines. Only available if **Show Grid** is selected. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Log Scale:** If this box is checked, the scale will be logarithmic.
- **Force 0:** Fixes the lower edge of the chart to zero on the y-axis. This option is not available when a logarithmic axis is used.
- **Static Min:** Sets a fixed minimum value for the axis. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Max:** Sets a fixed maximum value for the axis. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Step:** Sets a fixed interval for tick marks on the axis. If this setting results in more than 100 tick marks, the value used will be modified. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Center:** Sets a fixed value on the axis which will be positioned in the center of the plot area. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

## Show Title

By default, the label of the first expression defined is set as chart title. Clear the check box if you do not wish to have a chart title. The title may be defined as a calculated formula for dynamic update. Click *fx* to open the **Edit Expression** dialog.

## More.../Less...

Click this button to expand/collapse the foldout that contains additional tabs. Depending on if the **Dimensions** or **Expressions** field is active, different tabs are displayed.

## Combo Chart Properties: Presentation

Some options may not be available for all objects.

### Look

Click  to open the popup.

- **Top Angle:** Defines the vertical angle of the 3D view. The value must be an integer between 0 and 30.
- **Side Angle:** Defines the side angle of the 3D view. The value must be an integer between 0 and 45.

### Orientation

Sets the orientation of the chart.

## Color Style

Defines the color style on all plot colors in the chart. Click  to open the popup.

- **Persistent Colors:** Locks the colors assigned to each data point even if selections reduce the total number of data points. In this mode color representation will never change for a given data point, but there is a risk of having two adjacent bars or slices with the same color for different data points.
- **Repeat Last Color:** Select this check box to assign the last (18th) color to field values loaded as number 18 and forward. If this check box is left unselected, the 19th value (according to the original load order) will get the first color, the 20th value the second color, etc.

## Show Legend

Displays the legend in the chart. Click  to open the popup.

- **Legend Style:** Sets the legend style.
- **Vertical:** Sets the vertical alignment of the legend.
- **Line Spacing:** Specifies the distance between items in the legend.
- **Reverse Order:** To reverse the sort order of the legend mark this check box.
- **Wrap Cell Text:** If this check box is marked, the text of the legend items will be wrapped in two or more lines.

## Stacked Bars

Checking this option displays the bars stacked instead of grouped.

## Bar Distance

Enter a number or drag the slider to set the distance between the bars in the cluster.

## Cluster Distance

Enter a number or drag the slider to set the distance between clusters in the chart.

## Background

Sets the background of the chart. The following options are available:

- **Color:** Click  to select a color.
- **Image:** Click  to change the image.
- **Dynamic Image:** Enter a calculated expression to show dynamic background images that change with the selection.

## Plot Area Background

Sets the background of the plot area. The following options are available:

- **Color:** The plot area will have a colored background. Click  to select a color.
- **Image:** The plot area will have an image background. Click  to change the image.
- **Dynamic Image:** Enter a calculated expression to show dynamic background images that change with the selection.

## Plot Area Style

This control can be used to change the appearance of the plot area background. The following options are available:

- **Frame:** A frame is drawn around the plot area.
- **Shadow:** This options gives a shadow effect on the plot area background.
- **Minimal:** The plot area background is removed.

## Background Transparency

Enter a value in the box or drag the slider to set transparency for the chart.

## More.../Less...

Click this button to expand/collapse the foldout that contains additional tabs.

## General

- **Reverse Direction:** When this check box is marked, the values shown in the chart will be reversed, i.e. if the 10 highest values are shown and the box is checked the chart will then show the 10 lowest values.
- **Max Values Shown:** In this box, specify an upper limit for how many data points to show values for in the chart. If no limit is specified, values will be shown for all data points, which may affect the readability of the chart.
- **Suppress Zero-Values:** If this check box is marked, all combinations of the dimension fields returning zero or null from all expressions will be disregarded in the calculation. This option is selected by default.
- **Zero on Bars:** This setting is only applicable when **Suppress Zero-Values** is deselected. If the check box is marked and **Values on Data Points** is selected, zero values will appear as text above the data points. In other cases zero values will be suppressed.
- **Suppress Missing:** If this check box is marked, all combinations of the dimension fields associated with only null values in all fields in all expressions will be disregarded in the calculation. This option is selected by default. Turning it off can be useful only in special cases, e.g. if null values is to be counted in a chart.
- **Synchronize Zero for Expression Axes:** Synchronizes the zero level of the two y-axes (left/right or top/bottom).
- **Use Full Symbol Set:** This alternative makes more symbol representations available (rings, triangles, etc.)
- **Allow Thin Bars:** For charts with a non-continuous x-axis, QlikView will only display as many data points as can be accommodated in the plot area available. Remaining data points are truncated

from the chart. By default bars will be drawn with a minimum width of four pixels, so that they are clearly distinguishable. Mark this check box to allow bar width down to one pixel.

- **Show All Bars:** For charts with a non-continuous x-axis, QlikView will only display as many data points as can be accommodated in the plot area available. Remaining data points are truncated from the chart. Mark this check box to force plotting of all bars. The bars will be compressed and some data points may become obscured by others.
- **Vertical Numbers:** Shows the values vertically.
- **Plot Numbers on Segments:** Marking this check box will plot values on data points inside the segments instead of on top of them.
- **Popup Labels:** By selecting this check box the values of the dimensions and expressions will appear as a pop-up balloon when hovering with the cursor over data point in the chart.
- **Highlight:** This option is not supported for AJAX/WebView.

### Chart Scrolling

Click  to open the popup.

- **Chart Scrolling Popup:** Enable this check box to show a scroll control in place of the X-axis, when the number of bars exceeds the defined number. The scroll bar can be used to scroll the selection of the X-axis values that are displayed.
- **Calculation Conditions:** The expression entered here sets a condition to be fulfilled for the chart to be calculated. If the condition is not fulfilled, the text 'Calculation condition unfulfilled' will be displayed in the chart. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.

### Styles

- **Legend:** To set the color of the legend click . To set the font color of the legend click . To set the font type click .
- **Chart Title Style:** To set the font color of the chart title click . To set the font type click .
- **Caption Font:** To set the caption font type click .
- **Active Caption:** To set the background color for the active caption click . To set the text color click .
- **Inactive Caption:** To set the background color for the inactive caption click . To set the text color click .
- **Use Border:** Mark this check box in order to use a border around the sheet object. Click the  to set the color of the border.
- **Border Width:** Specify a value or drag the slider to set the width of the border. The width is specified in pixels.

- **Rounded Corners:** Click  to open the **Rounded Corners** popup.

 **Rounded Corners** is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.

- **Rounded Corners Popup:** Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected. Also select **Squareness** by entering a value.
- **Scroll Bar Background:** To set the scroll bar background color click .
- **Scroll Bar Slider:** To set the scroll bar slider color click .
- **Scroll Bar Width:** Specify a value or drag the slider to set the width of the scroll bar. This control affects both the width and the relative size of the scroll bar symbols.
- **Trendline Width:** Specify the width of the trendline.
- **Error Bar:** To set the error bar slider color click .
- **Error Bar Width:** Specify the width of the error bar.
- **Error Bar Thickness:** Specify the thickness of the error bar.
- **Reference Lines:**
  - **Reference Lines:** Add a reference line by clicking .
  - **Show Label in Chart:** Displays the label next to the reference line.
  - **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
  - **X-Axis:** Select this option if the reference line should originate from the x-axis.
  - **Expression:** The value at which the reference line should be drawn. Enter an expression you wish to use as start point.
  - **Line Weight:** Specifies the weight of the reference line.
  - **Line Style:** Specifies the style of the reference line.
  - **Line Color:** Specifies the color of the reference line.
  - **Use Show Condition:** The reference line will be shown or hidden depending on a conditional expression which will be evaluated each time the chart is to be drawn. The reference line will only be hidden when the expression returns FALSE.
  - **Condition:** Enter the conditional expression. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
- **Text:**
  - **Text in Chart:** Click  to add text in the chart.
  - **Text:** The text added in **Text in Chart** are displayed here.
  - **Tilt Angle:** Specify an angle between 0 and 360 degrees for the text. The default is 0.

- **Horizontal Align:** Sets the horizontal alignment.
- **On Top:** The text currently selected in the list will be forced to the foreground when drawing the chart.
- **Text Style:**
  - To set the background color for the text click .
  - To set the font color click . To set the font type click .
- **Size Position:** Sets the position and size of the text on the object.

## Combo Chart Properties: Caption

### Caption

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.  
The value may be entered as a calculated formula.

Click  to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

### More.../Less...

#### Icons in Caption

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!

- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Maximize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.
- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.  
Click  to open the popup.
- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Combo Chart Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.

- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.29 Radar Chart - AJAX/Webview

Radar charts could be described as line charts where the x-axis is wrapped around 360 degrees and with one y-axis for each x-value. The result is similar to a spider web or a radar screen.

### Radar Chart: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

Menu commands

| Command       | Details                                                         |
|---------------|-----------------------------------------------------------------|
| Properties... | Opens the <b>Properties</b> dialog for the active sheet object. |
| Notes         | Allows creating and sharing notes about the current object.     |

| Command              | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Detach               | The chart title is appended with the text "(Detached)" and the chart is no longer updated with selections made in the document (though selections may actually still be made from the chart). The command is available only if the chart is attached. By making a copy of a chart and detaching it, you may make direct comparisons between the copy and the original.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Attach               | Attaches a detached chart. The chart becomes dynamically linked to the data. The command is available only if the chart is detached.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Set Reference        | This option sets a chart reference, such as a fixed plot of the chart with the current selections. When further selections are made in the document the reference plot remains, dimmed in the background. Chart axes will be adjusted to always include the maximum of the background data set and the current data set. The current data set is always plotted on top of the reference plot. Some portions of the reference plot may be obscured by the current data set plot. The display of reference chart plots is only possible in some chart types, such as bar charts, line charts, combo charts, radar charts, scatter charts, grid charts and gauge charts with needles. It is not possible to set a reference for a chart that contains a drill-down or a cyclic group. The reference will be lost when closing the document or when reloading data. The maximum number of objects that can be included when using the <b>Set Reference</b> option is 500. |
| Clear Reference      | This command is replaced with the <b>Set Reference</b> command when a reference is set. By choosing it the previously set reference will be cleared and the chart will revert to normal plot mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Clear All Selections | Clears all the current selections in the active sheet object. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Copy                 | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Print...             | Opens the selected sheet object(s) in tabular format in another browser window.<br><br>Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Send to Excel        | Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Export...            | Opens the <b>Save as</b> dialog where path, file name and (table) file type for the exported data content can be specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Command     | Details                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fast Change | Makes it possible to change the current chart into another chart type. Clicking on the  icon in the object caption (if shown) produces the same result. Only available if <b>Fast Type Change in Chart</b> has been enabled on the <b>Caption</b> tab of the <b>Properties</b> dialog.                 |
| Minimize    | Iconizes the object. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if minimizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                     |
| Restore     | Restores a minimized or maximized object to its previous size and location. Double-clicking the icon of a minimized object or clicking the  icon in the object caption (if shown) of a maximized object produces the same result. This command is available only for minimized or maximized objects. |
| Maximize    | Enlarges the object to fill the sheet. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if maximizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                  |
| Remove      | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                                                                             |

## Radar Chart Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

### Dimensions

Choose dimensions in the drop-down list. To add a dimension, click . Select a dimension in the drop-down. Use the  icon to move items in the list. The  icon removes items from the list. For more settings, click the **More...** button.

### Dimension

- **Enable Conditional:** Marking this check box hides or shows the dimension dynamically, depending on the value of a condition expression entered, by clicking the  button in the edit box below.
- **Dimension:** Displays the currently selected dimension.
- **Show Label:** Mark this check box to show a dimension label (the field name) on the x-axis.
- **Suppress Null Values:** If this check box is marked, the field selected as **Dimension** above will not be displayed in the chart if its value is NULL.
- **Show All Values:** Mark this check box to show all the dimension field values in the chart, including logically excluded values.
- **Show Axis Labels:** Mark this check box to show legend (names of field values) on the x-axis for the selected dimension field.

- **Limit Axis Label Characters:** Mark this check box to limit the length of the dimension value strings to be shown on axes and in the chart legend. Specify the number of characters in the input field, or drag the slider to the desired value. Truncated values will be followed by ... in the chart. This option can be used independently to the other options in this group.
- **Trellis Setting First Dimension:** Marking this check box will enable the trellis chart, where an array of charts that are based on the chart's first dimension are displayed.
- **Fixed Number of Columns:** Enter the number of columns you want the trellis chart to display. Specify the number of columns in the input field, or drag the slider to the desired value.
- **Fixed Number of Rows:** Enter the number of rows you want the trellis chart to display. Specify the number of rows in the input field, or drag the slider to the desired value.
- **Second Dimension:** Enables the second dimension in the trellis chart. If a secondary dimension is used, the first dimension values will be displayed as columns in the trellis matrix, whereas the secondary dimension values will be displayed as rows in the trellis matrix.

## Sort

Sets the sort order of the values in the sheet object. Some sort options may not be available for all sheet objects.

If more than one sort order is specified, the sort order will be state, expression, frequency, numeric, text, load order. **State** refers to the logical state (selected, optional, or excluded).

- **Primary Sort: Y-Value:** Sets whether the dimension values should be sorted according to the numeric value of the y-axis. This option is not available for calculated dimensions. **Frequency:** Sorts the field values by frequency (number of concurrences in the table). **Numeric Value:** Sorts the field values by their numeric values. **Text:** Sorts the field values in alphabetical order. **Load Order:** Sorts the field values by the initial load order.
- **Secondary Sort: Frequency:** Sorts the field values by frequency (number of concurrences in the table).  
**Numeric Value:** Sorts the field values by their numeric values.  
**Text:** Sorts the field values in alphabetical order.  
**Load Order:** Sorts the field values by the initial load order.
- **Sort by Expression:** Sorts the field values according to the expression entered.
- **Keep Selected on Top:** The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog. Enable this to keep the selected values on top.

## Limits

- **Restrict which values are displayed using the first expression:** These properties are used to determine how many dimension values are displayed in the chart, according to settings made below.
- **Show only:**  
Select this option if you want to show the **First**, **Largest** or **Smallest** x number of values. If this option is set to 5, there will be five values displayed. If the dimension has **Show Others** enabled, the Others segment will take up one of the five display slots.
  - The **First** option will return the rows based on the options selected on the **Sort** tab of the property dialog. If the chart is a Straight Table, the rows will be returned based on the

primary sort at the time. In other words, a user can change the values display by double-clicking on any column header and making that column the primary sort.

- The **Largest** option returns the rows in descending order based on the first expression in the chart. When used in a Straight Table, the dimension values shown will remain consistent while interactively sorting the expressions. The dimensions values will (may) change when the order of the expressions is changed.
- The **Smallest** option returns the rows in ascending order based on the first expression in the chart. When used in a Straight Table, the dimension values shown will remain consistent while interactively sorting the expressions. The dimensions values will (may) change when the order of the expressions is changed.
- Enter the number of values to display.
- The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- Select **Include Boundary Values** to include the dimension value that contains the comparison value.
- **Show only values that are:** Select this option to display all dimensions values that meet the specified condition for this option. Select to display values based on a percentage of the total, or on an exact amount. The **relative to the total** option enables a relative mode which is similar to the **Relative** option on the **Expressions** tab of the property dialog. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Show only values that accumulate to:** When this option is selected, all rows up to the current row are accumulated, and the result is compared to the value set in the option. The **relative to the total** option enables a relative mode which is similar to the **Relative** option on the **Expressions** tab of the property dialog, and compares the accumulated values (based on first, largest or smallest values) to the overall total. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Show Others:** Enabling this option will produce an **Others** segment in the chart. All dimension values that do not meet the comparison criteria for the display restrictions will be grouped into the **Others** segment. If there are dimensions after the selected dimension, **Collapse Inner Dimensions** will control whether individual values for the subsequent / inner dimensions display on the chart. In the **Label** field, enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text.

The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog. If there are dimensions after the selected dimension, **Collapse Inner Dimensions** will control whether individual values for the subsequent / inner dimensions display on the chart.
- **Show Total:** The chart will display a total for the selected dimension when this option is enabled. This total behaves differently than the expression total, which is still configured on the **Expressions** tab of the property dialog. **Label:** Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Use Global Grouping Mode:** The option only applies to inner dimensions. When this option is enabled the restrictions will be calculated on the selected dimension only. All previous dimensions will be ignored. If this is disabled, the restrictions are calculated based on all preceding dimensions.

## Axis

- **Show Axis:** Check this box to show the axis.
- **Axis Width:** Enter the width of the axis and its tick marks, or drag the slider to the desired value.
- **Major Label:** Select **Horizontal**, **Vertical** or **Tilted** display of the major labels.
- **Minor Label:** Select **Horizontal**, **Vertical** or **Tilted** display of the minor labels.
- **Show Grid:** Check this box to show a grid in the chart originating from the tick marks of the x-axis. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Show Minor Grid:** Check this box to show minor lines in-between the grid lines. Only available if **Show Grid** is selected. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Stagger Labels:** Select this option to stagger x-axis labels when they become too many to show side by side.
- **Reverse Stagger:** X-axis labels are normally staggered bottom-up from left to right. When marking this check box, the stagger will be reversed to top-down.
- **Continuous X:** Sets the x-axis to be continuous, i.e. it will be interpreted numerically and shown with numerically correct intervals.
- **Force 0:** Fixes the lower edge of the chart to zero on the y-axis. This option is not available when a logarithmic axis is used.
- **Static Min:** Sets a fixed minimum value for the axis. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Max:** Sets a fixed maximum value for the axis. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Step:** Sets a fixed interval for tick marks on the axis. If this setting results in more than 100 tick marks, the value used will be modified. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Backcast:** By entering an integer in the edit field, you force the x-axis to be extended to the left of the actual data points plotted. This is useful when using trend lines. The backcast line will be dotted. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Forecast:** By entering an integer in the edit field, you force the x-axis to be extended to the right of the actual data points plotted. This is useful when using trendlines. The forecast line will be dotted. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

## Expressions

Choose expressions in the drop-down list. To add an expression, click . Select an expression from the drop-down. Use the  icon to move items in the list. The  icon removes items from the list. For more information click the **More...** button.

## Expression

- **Enable:** Marking this check box will enable the selected expression. If the box is not marked, the expression will not be used at all.

- **Conditional:** Marking this check box hides or shows the expression dynamically, depending on the value of a condition expression entered, by clicking the  $fx$  button in the edit box below.
- **Label:** The label of the expression. Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text. The value may be entered as a calculated formula. Click  $fx$  to open the **Edit Expression** dialog.
- **Expression:** Displays the currently selected expression.
- **Comment:** Enter a comment to describe the purpose and function of the expression. The value may be entered as a calculated formula. Click  $fx$  to open the **Edit Expression** dialog.
- **Invisible:** Hides the expression.
- **Show in Percent (Relative):** The chart shows the result in percent instead of absolute numbers.
- **Accumulate Expression:**

Check this box to accumulate expressions. Click  to open the popup.

- **Accumulation Popup:** Select one of the options to decide whether the values in the sheet object should be accumulated or not.
  - **Accumulate:** In an accumulated chart, each y-value is added to the y-value of the following x-value.
  - **No Accumulation:** The y-values of the selected chart expression will not be accumulated.
  - **Full Accumulation:** Each y-value accumulating all previous y-values of the expression. Full accumulation does not work if the chart trellis is enabled.
  - **Accumulation Steps:** Enter a number in the box or drag the slider to set the number of y-values in the expression to be accumulated.
- **Show in Legend:** When several expressions are used, this option displays a legend showing the expressions and their corresponding colors next to the chart.
- **Line & Symbol Settings:** Check this box to make layout settings for lines and symbols. Click  to open the popup.
  - **Line & Symbol Settings Popup:**
    - Line: Make settings for the layout of lines.
    - Symbol: Make settings for the layout of used symbols.
- **Value Display Settings:**
  - **Show Values on Datapoints:** Mark this check box to display the result of the expression as text on top of the data points.
  - **Text as Popup:** Mark this check box to have the result of the expression shown in the popup balloon messages appearing when hovering over a data point in a chart in the layout. This option can be used with or without any of the other display options. It is thus possible to have an expression that does not appear in the chart itself, but only in hover popups.
  - **Text on Axis:** Plots the result of the expression at each x-axis value, the axis and the axis labels.

### Attribute Expression Styles

- **Background Color:** Define an attribute expression for calculating the basic plot color of the data point. The expression used should return a valid color representation (a number representing the Red, Green and Blue components as defined in Visual Basic) which is typically achieved by using one of the special chart color functions. If the result of the expression is not a valid color representation, black will be used.
- **Line Style:** Define an attribute expression for calculating the line style for the line or line segment associated with the data point. The relative width of the line can be controlled by including a tag <Wn> where n is a multiplying factor to be applied on the default line width of the chart. The number n must be a real number between 0.5 and 8. Example: <W2.5>. The style of the line can be controlled by including a tag <Sn> where n is an integer between 1 and 4 indicating the style to be used (1=continuous, 2= dashed, 3=dotted, 4=dashed/dotted). Example: <S3>. The <Wn> and <Sn> tags can be freely combined, but only the first occurrence of each counts. The tags must be enclosed by single quotations.
  - **Number Format Tab:** Each field has a default number format which can be set in the Document Properties: Number page. It is however possible to use a separate number format for an individual sheet object. This property page applies to the active object and contains the following controls for formatting values:
    - **Number Format:** Choose a number format from the alternatives below.
    - **Default:** Both numbers and text. Numbers are shown in original format.
    - **Number:** Shows numeric values with the number of digits set in the **Precision** field.
    - **Integer:** Shows numeric values as integers.
    - **Fixed to:** Shows numeric values as decimal values with the number of decimal digits set in the **Decimals** field.
    - **Money:** Shows values in the format set in the **Format Pattern** field. The default format is the Windows Currency setting.
    - **Date:** Shows values that can be interpreted as dates in the format set in the **Format Pattern** field.
    - **Time:** Shows values that can be interpreted as time in the format set in the **Format Pattern** field.
    - **Timestamp:** Shows values that can be interpreted as date + time in the format set in the **Format Pattern** field.
    - **Interval:** Shows time as sequential time increments (e.g. format = mm shows the value as the number of minutes since calendar start (1899:12:30:24:00)).
    - **Format Pattern:** The format code that further specifies the display format of the field. **ISO** sets the format to the ISO standard. Only valid for **Date**, **Time**, **Timestamp** and **Interval**. **Sys** sets the format to the system settings.
    - **Precision:** The number of digits that will be displayed.
    - **Decimals:** Sets the number of decimals included.
    - **Decimals Separator:** Sets the symbol for decimal separators.
    - **Thousand Separator:** Sets the symbol for thousand separators.

- **In Percent:** Shows formatting in percentage instead of absolute numbers. The setting is only available for **Number**, **Integer** and **Fixed to**.
- **Preview:** Shows a preview of the number format specified above.

### Axis

- **Show Axis:** Check this box to show the axis.
- **Axis Width:** Enter the width of the axis and its tick marks, or drag the slider to the desired value.
- **Split Axis:** Check this box to split the y-axis into two parts, thus creating an impression of two charts sharing a common x-axis.
- **Position:** Choose **Left** or **Right** position. If **Split Axis** was selected, choose **Top** or **Bottom** position.
- **Show Grid:** Check this box to show a grid in the chart originating from the tick marks of the x-axis. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Show Minor Grid:** Check this box to show minor lines in-between the grid lines. Only available if **Show Grid** is selected. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Log Scale:** If this box is checked, the scale will be logarithmic.
- **Force 0:** Fixes the lower edge of the chart to zero on the y-axis. This option is not available when a logarithmic axis is used.
- **Static Min:** Sets a fixed minimum value for the axis. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Max:** Sets a fixed maximum value for the axis. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Step:** Sets a fixed interval for tick marks on the axis. If this setting results in more than 100 tick marks, the value used will be modified. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Center:** Sets a fixed value on the axis which will be positioned in the center of the plot area. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

### Show Title

By default, the label of the first expression defined is set as chart title. Clear the check box if you do not wish to have a chart title. The title may be defined as a calculated formula for dynamic update. Click *fx* to open the **Edit Expression** dialog.

### More.../Less...

Click this button to expand/collapse the foldout that contains additional tabs. Depending on if the **Dimensions** or **Expressions** field is active, different tabs are displayed.

## Radar Chart Properties: Presentation

This section describes **Radar Chart** properties.

### Look

Select one of the available looks in the drop-down.

## Show Legend

Displays the legend in the chart. Click  to open the popup.

### Legend Settings Popup

- **Legend Style:** Sets the legend style.
- **Vertical:** Sets the vertical alignment of the legend.
- **Line Spacing:** Specifies the distance between items in the legend.
- **Reverse Order:** To reverse the sort order of the legend mark this check box.
- **Wrap Cell Text:** If this check box is marked, the text of the legend items will be wrapped in two or more lines.

## Stacked

Checking this option displays data points stacked.

## Line Width

Sets the line width for lines.

## Symbol Size

Sets the size of the symbols, when such are used.

## Background

Sets the background of the chart. The following options are available:

- **Color:** Click  to select a color.
- **Image:** Click  to change the image.
- **Dynamic Image:** Click  to set the dynamic image.
  - Enter a calculated expression to show dynamic background images that change with the selection.

## Background Transparency

Click  to set the background transparency. Enter a value in the box or drag the slider to set the transparency.

## More.../Less...

This section describes the **General** property.

### General

- **Reverse Direction:** When this check box is marked, the values shown in the chart will be reversed, i.e. if the 10 highest values are shown and the box is checked the chart will then show the 10 lowest values.

- **Max Values Shown:** In this box, specify an upper limit for how many data points to show values for in the chart. If no limit is specified, values will be shown for all data points, which may affect the readability of the chart.
- **Suppress Zero-Values:** If this check box is marked, all combinations of the dimension fields returning zero or null from all expressions will be disregarded in the calculation. This option is selected by default.
- **Suppress Missing:** If this check box is marked, all combinations of the dimension fields associated with only null values in all fields in all expressions will be disregarded in the calculation. This option is selected by default. Turning it off can be useful only in special cases, e.g. if null values is to be counted in a chart.
- **Synchronize Zero for Expression Axes:** Synchronizes the zero level of the two y-axes (left/right or top/bottom).
- **Use Full Symbol Set:** This alternative makes more symbol representation available (rings, triangles etc.)
- **Semi-transparent:** Check this box to make filled lines to be drawn semi-transparent.
- **Vertical Numbers:** Shows the values vertically.
- **Plot Numbers on Segments:** Marking this check box will plot values on data points inside the segments instead of on top of them.
- **Popup Labels:** By selecting this check box the values of the dimension(s) and expression(s) will appear as a pop-up balloon when hovering with the cursor over data point in the chart.
- **Highlight:** If this check box is marked hovering with the mouse over a line or symbol in it will result in the line or symbol being highlighted for better overview. The highlighting applies also in the legend where applicable.
- **Calculate Conditions:** The expression entered here sets a condition to be fulfilled for the chart to be calculated. If the condition is not fulfilled, the text 'Calculation condition unfulfilled' will be displayed in the chart. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

## Styles

- **Legend:** To set the color of the legend click . To set the font color click . To set the font type click **Aa**.
- **Chart Title Style:** To set the font color of the chart title click . To set the font type click **Aa**.
- **Caption Font:** To set the caption font type click **Aa**.
- **Active Caption:** To set the background color for the active caption click . To set the text color click .
- **Inactive Caption:** To set the background color for the inactive caption click . To set the text color click .

- **Use Border:** Mark this check box in order to use a border around the sheet object. Click the  to set the color of the border.
- **Border Width:** Specify a value or drag the slider to set the width of the border. The width is specified in pixels.
- **Rounded Corners:**
  - Click  to open the **Rounded Corners** popup.

 **Rounded Corners** is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.

- Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected. Also select **Squareness** by entering a value.
- **Scroll Bar Background:** To set the scroll bar background color click .
- **Scroll Bar Slider:** To set the scroll bar slider color click .
- **Scroll Bar Width:** Specify a value or drag the slider to set the width of the scroll bar. This control affects both the width and the relative size of the scroll bar symbols.
  - **Reference Lines:**
    - **Reference Lines:** Add a reference line by clicking .
    - **Show Label in Chart:** Displays the label next to the reference line.
    - **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
    - **X-Axis:** Select this option if the reference line should originate from the x-axis.
    - **Expression:** The value at which the reference line should be drawn. Enter an expression you wish to use as start point.
    - **Line Weight:** Specifies the weight of the reference line.
    - **Line Style:** Specifies the style of the reference line.
    - **Line Color:** Specifies the color of the reference line.
    - **Use Show Condition:** The reference line will be shown or hidden depending on a conditional expression which will be evaluated each time the chart is to be drawn. The reference line will only be hidden when the expression returns FALSE.
    - **Condition:** Enter the conditional expression. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
  - **Text:**
    - **Text in Chart:** Click  to add text in the chart.
    - **Text:** The text added in **Text in Chart** are displayed here.

- **Tilt Angle:** Specify an angle between 0 and 360 degrees for the text. The default is 0.
- **Horizontal Align:** Sets the horizontal alignment.
- **On Top:** The text currently selected in the list will be forced to the foreground when drawing the chart.
- **Text Style:**
  - To set the background color for the text click .
  - To set the font color click . To set the font type click .
- **Size Position:** Sets the position and size of the text on the object.

## Radar Chart Properties: Caption

This section describes **Radar Chart** properties.

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.  
The value may be entered as a calculated formula.

Click  to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

## More.../Less...

This section describes **More.../Less...** properties.

### Icons in Caption

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a

new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!

- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Maximize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.
- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.  
Click  to open the popup.
- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Radar Chart Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.

- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.30 Gauge Chart - AJAX/WebView

Gauge charts are used to display the value of a single expression without dimensions.

### Gauge Chart: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

Menu commands

| Command       | Details                                                         |
|---------------|-----------------------------------------------------------------|
| Properties... | Opens the <b>Properties</b> dialog for the active sheet object. |
| Notes         | Allows creating and sharing notes about the current object.     |

| Command              | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Detach               | The chart title is appended with the text “(Detached)” and the chart is no longer updated with selections made in the document (though selections may actually still be made from the chart). The command is available only if the chart is attached. By making a copy of a chart and detaching it, you may make direct comparisons between the copy and the original.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Attach               | Attaches a detached chart. The chart becomes dynamically linked to the data. The command is available only if the chart is detached.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Set Reference        | This option sets a chart reference, such as a fixed plot of the chart with the current selections. When further selections are made in the document the reference plot remains, dimmed in the background. Chart axes will be adjusted to always include the maximum of the background data set and the current data set. The current data set is always plotted on top of the reference plot. Some portions of the reference plot may be obscured by the current data set plot. The display of reference chart plots is only possible in some chart types, such as bar charts, line charts, combo charts, radar charts, scatter charts, grid charts and gauge charts with needles. It is not possible to set a reference for a chart that contains a drill-down or a cyclic group. The reference will be lost when closing the document or when reloading data. The maximum number of objects that can be included when using the <b>Set Reference</b> option is 500. |
| Clear Reference      | This command is replaced with the <b>Set Reference</b> command when a reference is set. By choosing it the previously set reference will be cleared and the chart will revert to normal plot mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Clear All Selections | Clears all the current selections in the active sheet object. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Copy                 | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Print...             | Opens the selected sheet object(s) in tabular format in another browser window.<br><br>Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Send to Excel        | Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Export...            | Opens the <b>Save as</b> dialog where path, file name and (table) file type for the exported data content can be specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Command     | Details                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fast Change | Makes it possible to change the current chart into another chart type. Clicking on the  icon in the object caption (if shown) produces the same result. Only available if <b>Fast Type Change in Chart</b> has been enabled on the <b>Caption</b> tab of the <b>Properties</b> dialog.                 |
| Minimize    | Iconizes the object. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if minimizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                     |
| Restore     | Restores a minimized or maximized object to its previous size and location. Double-clicking the icon of a minimized object or clicking the  icon in the object caption (if shown) of a maximized object produces the same result. This command is available only for minimized or maximized objects. |
| Maximize    | Enlarges the object to fill the sheet. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if maximizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                  |
| Remove      | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                                                                             |

## Gauge Chart Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

## Expressions

Choose expressions in the drop-down list. To add an expression, click . Select an expression from the drop-down. Use the  icon to move items in the list. The  icon removes items from the list. For more information click the **More...** button.

## Expression

- **Enable:** Marking this check box will enable the selected expression. If the box is not marked, the expression will not be used at all.
- **Conditional:** Marking this check box hides or shows the expression dynamically, depending on the value of a condition expression entered, by clicking the *fx* button in the edit box below.
- **Label:**
  - The label of the expression. Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text.
  - The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Expression:** Displays the currently selected expression.
- **Comment:** Enter a comment to describe the purpose and function of the expression.

- **Number Format Tab:** Each field has a default number format which can be set in the Document Properties: Number page. It is however possible to use a separate number format for an individual sheet object. This property page applies to the active object and contains the following controls for formatting values:
  - **Number Format:** Choose a number format from the alternatives below.
  - **Default:** Both numbers and text. Numbers are shown in original format.
  - **Number:** Shows numeric values with the number of digits set in the **Precision** field.
  - **Integer:** Shows numeric values as integers.
  - **Fixed to:** Shows numeric values as decimal values with the number of decimal digits set in the **Decimals** field.
  - **Money:** Shows values in the format set in the **Format Pattern** field. The default format is the Windows Currency setting.
  - **Date:** Shows values that can be interpreted as dates in the format set in the **Format Pattern** field.
  - **Time:** Shows values that can be interpreted as time in the format set in the **Format Pattern** field.
  - **Timestamp:** Shows values that can be interpreted as date + time in the format set in the **Format Pattern** field.
  - **Interval:** Shows time as sequential time increments (e.g. format = mm shows the value as the number of minutes since calendar start (1899:12:30:24:00)).
  - **Format Pattern:** The format code that further specifies the display format of the field. ISO sets the format to the ISO standard. Only valid for **Date**, **Time**, **Timestamp** and **Interval**. Sys sets the format to the system settings.
  - **Precision:** The number of digits that will be displayed.
  - **Decimals:** Sets the number of decimals included.
  - **Decimals Separator:** Sets the symbol for decimal separators.
  - **Thousand Separator:** Sets the symbol for thousand separators.
  - **In Percent:** Shows formatting in percentage instead of absolute numbers. The setting is only available for **Number**, **Integer** and **Fixed to**.
  - **Preview:** Shows a preview of the number format specified above.

## Actions

Choose actions in the drop-down list. To add an action, click . Select an action from the drop-down.

Use the  icon to move items in the list. The  icon removes items from the list. Click  to open the **Action Settings** popup.

- **Action Settings Popup:** Select action **Type** and **Subtype** in the drop-down lists:
  - **Selection:**
    - **Select in Field:** Selects the values and fields that are specified. In the **Search String** you can specify a search mask, e.g. (A|B) will select both A and B.
    - **Select Excluded:** Selects the excluded values in the specified field.

- **Select Possible:** Selects the possible values in the specified field.
- **Toggle Select:** Toggles between the current selection and the specified **Field** and **Search String**. In the **Search String** you can specify a search mask, e.g. (A|B) will select both A and B.
- **Forward:** Goes one step forward in the list of selections.
- **Back:** Goes back one step in the list of selections.
- **Pareto Select:** Makes a pareto selection in the specified field based on an expression and percentage. This type of selection is used to select the top contributors to a measure, typically in line of a general 80/20 rule. For example, to find the top customers that contribute to 80% of the turnover, Customer should be used as field, sum(Turnover) should be used as expression and 80 should be used as percentage.
- **Lock Field:** Locks the selections in the specified field.
- **Lock All:** Locks all values in all fields.
- **Unlock Field:** Unlocks the selections in the specified field.
- **Unlock All:** Unlocks all values in all fields.
- **Unlock and Clear All:** Unlocks all values and clears all selections in all fields.
- **Clear Other Fields:** Clears all related fields except the one specified.
- **Clear All:** Clears all selections except locked ones.
- **Clear Field:** Clears a specific field.
- **Layout:**
  - **Activate Object:** Activates the object specified by **Object ID**. This function does not work in Ajax client.
  - **Activate Sheet:** Activates the sheet specified by **Sheet ID**.
  - **Activate Next Sheet:** Opens the next sheet in the document.
  - **Activate Previous Sheet:** Opens the previous sheet in the document.
  - **Minimize Object:** Minimizes the object specified by **Object ID**.
  - **Maximize Object:** Maximizes the object specified by **Object ID**.
  - **Restore Object:** Restores the object specified by **Object ID**.
- **Bookmark:**
  - **Apply Bookmark:** Applies a bookmark specified by **Bookmark ID**. If two bookmarks have the same ID, the document bookmark is applied. To apply the server bookmark specify Server\bookmarkID.
  - **Create Bookmark:** Creates a bookmark from the current selection. Specify **Bookmark ID** and **Bookmark Name**. Select **Hidden** to create a hidden bookmark.
  - **Replace Bookmark:** Replaces the bookmark specified by **Bookmark ID** with the current selection.
- **Print:**
  - **Print Object:** Prints the object specified by **Object ID**. Specify the **Printer name** if the object should be sent to another printer than the default printer. (Not available as document and sheet trigger.)

- **Print Sheet:** Prints the sheet specified by **Sheet ID**. (Not available as document and sheet trigger.) This function does not work in AJAX client.
- **Print Report:** Prints the report specified by **Report ID**. Specify the **Printer name** if the report should be sent to another printer than the default printer. Mark the check box **Show Print Dialog** if you want the Windows print dialog to be shown. (Not available as document and sheet trigger.)
- **External:**
  - Some clients may not handle this setting!
    - **Export:** Exports a table containing a specific set of fields, but only those records that are applicable according to the made selection are exported. Click on the **Setup** button on the **Actions** page to open the **Export Action Settings** dialog. This is not available as document or sheet trigger.

*This function does not work in AJAX client.*

- **Launch:** Launches an external program. The following settings can be configured in the **Actions** dialog:
  - **Application:** Click on **Browse...** to find the application that should be launched. (Not available as document and sheet trigger.)
  - **Filename:** Enter the path to the file that should be opened with the application specified above. (Not available as document and sheet trigger.)
  - **Parameters:** Specify parameters for the command line from which the application is started. (Not available as document and sheet trigger.)
  - **Working Directory:** Sets the working directory for the application to be launched. (Not available as document and sheet trigger.)
  - **Exit application when QlikView is closed:** Forces the application to be closed when QlikView is exited. (Not available as document and sheet trigger.)

*This function does not work in AJAX client.*

- **Open URL:** You can use **Open URL** to open a URL to a QlikView document from within another QlikView document (document chaining). This setting opens the URL in the default web browser. This function cannot be used as a document and sheet trigger. If using **Open URL**, make sure to enter the document name in the action-string in lower case. Where possible, use **Open QlikView Document** instead of **Open URL**.

*The use of Javascript in URLs is prevented by default. You can allow Javascript in URLs by changing the `PreventJavaScriptInObjectActions` parameter in the `custom.config` file.*

- **Open QlikView Document:** You can use **Open QlikView Document** to open a QlikView document from within another QlikView document (document chaining). This function cannot be used as a document or sheet trigger. For more information, see *Document chaining examples (page 1775)*.
- **Run Macro:** Enter the path and name of the macro to be run. Type any name for which it is possible to later create a macro in the **Edit Module** dialog, or a **calculated expression** for dynamic update.
- **Set Variable:** Assigns a value to the specified variable.
- **Show Information:** Shows the associated information, such as a text file or an image for the field specified by **Field**. This function does not work in AJAX client.
- **Close This Document:** Closes the active QlikView document.
- **Reload:** Performs a reload on the current document. This function does not work both in AJAX client and IE-plugin.
- **Dynamic Update:** Performs a dynamic update of the data in the currently loaded document. The statement for the dynamic update is to be entered in the **Statement** field.

The intended usage of Dynamic Update allows a QlikView Administrator to feed limited amounts of data in to a QlikView document from a single source without running a reload of the document. Analysis can then be performed by multiple clients connecting to the QlikView Server.

*The uploaded information is stored in RAM only so any data added or updated using Dynamic Update will be lost if a reload of the document is performed.*

The following grammar describes the possible statements and their components that can be used with the Dynamic Update feature:

- statements ::= statement { “,” statement }
- statement ::= insert\_statement | update\_statement | delete\_statement | begin\_transaction\_statement | commit\_transaction\_statement
- insert\_statement ::= "INSERT" "INTO" ("\*" | table\_name) field\_list "VALUES" value\_list { “,” value\_list } ["KEY" ["AUTO" | (" field\_list ")]] ["REPLACE" (["WITH" "ONE" | "EACH") ]]
- update\_statement ::= "UPDATE" ("\*" | table\_name) set\_clause { “,” | set\_clause } "WHERE" condition ["AUTO" "INSERT"]
- delete\_statement ::= "DELETE" "FROM" ("\*" | table\_name) "WHERE" condition
- begin\_transaction\_statement ::= "BEGIN" ("TRANSACTION" | "TRAN") [trans\_name]
- commit\_transaction\_statement ::= "COMMIT" ["TRANSACTION" | "TRAN"] [trans\_name]
- table\_name ::= identifier | quoted\_name

- `field_list ::= "(" field_name {" ," field_name } ")"`
- `value_list ::= "(" value {" ," value } ")"`
- `set_clause ::= "SET" field_name "=" any_valid_non_aggregated_qlikview_expression`
- `field_name ::= identifier | quoted string`
- `value ::= identifier | any_qlikview_number | quoted string`
- `condition ::= any_valid_non_aggregated_qlikview_expression`
- `identifier ::= any_qlikview_identifier`
- `quoted_string ::= "[" [^]]+ "]"`

**Example:**

```
UPDATE AbcTable SET Discount = 123 WHERE AbcField=1
```

*To use this feature, Dynamic Update must be allowed both on the Document and on the Server.*

**Document chaining examples**

You can use **Open QlikView Document** to create document chaining.

The following settings can be applied:

- **Transfer State:** to transfer the selections from the original document to the destination document. The destination document will first be cleared of selections.
- **Apply state on top of current:** to retain the destination document's selections and apply the original document's selections on top of them.

*Using **Apply state on top of current** can return unexpected results if the selections made in the two documents are conflicting.*

- **Open in same Window:** to open the new document in the same browser tab when using the AJAX ZFC client.

*Open QlikView Document action is not supported for non domain users when using the QlikView plug-in.*

QlikView documents: The extension of the destination file must be included. Relative paths to navigate from one QlikView document to another are supported in all clients, as long as the chained documents are stored in the same folder structure (mount).

The following examples show how to write the file path to the destination file:

**Example:** File located in the same folder structure (same mount).

- If the destination file is in the same folder:  
*DestinationDoc.qvw*
- If the destination file is in a sub folder:  
*SubFolder/DestinationDoc.qvw*

- If the destination file is in an upper folder:  
`../DestinationDoc.qvw`
- If the destination file is in an upper and parallel folder:  
`../ParallelFolder/DestinationDoc.qvw`

**Example:** File located in a different folder structure (different mount). The relative path between different mounts is supported in the Ajax client only.

- If the destination file is in a different mount:  
`../DifferentMount/DestinationDoc.qvw`

**Example:** Using the mount path to point to a QlikView document. Setting the path to mounted folders is supported in the Ajax client only.

- If the destination file is in the same mounted folder:  
`\Mount\DestinationDoc.qvw`
- If the destination file is in a different mounted folder:  
`\DifferentMount\DestinationDoc.qvw`

*Document chaining with mounted folders does not work with the QlikView plug-in.*

**Example:** Using the absolute path to point to a QlikView document. The use of absolute paths for document chaining is supported in the Ajax client and in QlikView Desktop.

- Absolute path to the Local Root folder or mount:  
`C:\...\DestinationDoc.qvw`
- Absolute path to a Network Share:  
`\\SharedStorage\...\DestinationDoc.qvw`

QlikView apps in the Qlik Sense Cloud hub: you need the AppId, not the path. Apps need to be prepared and updated in QlikView Desktop. The AppId is found in the URL when the app is open in the hub.

#### **Example**

If the URL is

`https://qcs.us.qlikcloud.com/qv/opendoc.htm?document=1cc71b323f172f93a8121ce1456cdg`. Then the AppId is `1cc71b323f172f93a8121ce1456cdg`.

#### Show title

By default, the label of the first expression defined is set as chart title. Clear the check box if you do not wish to have a chart title. The title may be defined as a calculated formula for dynamic update. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

#### More.../Less...

Click this button to expand/collapse the foldout that contains additional tabs.

## Gauge Chart Properties: Presentation

### Presentation

- **Look:** Select one of the available looks in the drop-down.
  - **Gauge Min:** Specifies the minimum value of the gauge. This corresponds to the bottom position of the gauge indicator.
  - **Gauge Max:** Specifies the maximum value of the gauge. This corresponds to the top position of the gauge indicator.
  - **Gauge Segment Settings:** In this group you define the segments making up the gauge. All gauges except LED style gauges must have at least one segment. For circular and linear gauges the segments make up differently colored areas in the gauge background. For traffic light gauges each segment corresponds to one light. A list of segments is shown and you may select one segment in the list to change its properties. Select a segment in the drop-down, to add a segment click .
- Click  to select a color on the bound. Click  to remove items from the list. Click  to open the popup.
- **Autowidth Segments:** If this check box is marked, the segment bounds will be calculated automatically based on the gauges Min value, Max value and the number of segments defined.
  - **Logarithmic Scale:** If this check box is marked, the gauge scale will be logarithmic.
  - **Relative Segment Limits:** If this option is selected the segment bounds can be entered as numbers between 0 and 1 indicating a fraction of the total range between the Min and Max values.
  - **Show Segment Outlines:** Shows the outlines of the gauge segments
  - **Show Segment Boundaries:** If this check box is marked outlines will be made in the segment boundaries of circular and linear gauges.
  - **Segments:** Click  to add segments to the gauge.
    - **Background:** Sets the background of the chart. The following options are available:
    - **Color:** Click  to select a color.
    - **Image:** Click  to change the image.
  - **Dynamic Image:** Enter a calculated expression to show dynamic background images that change with the selection.
  - **Background Transparency:** Enter a value in the box or drag the slider to set transparency for the chart.

### More.../Less...

- **General:** General Tab Speedometer and Circular Look.
- **Show Gauge Indicator:** Shows the gauge value by means of a needle indicator.
- **Indicator Style:** Specifies the style of the needle.

- **Fill Gauge to Value Only:** Shows the gauge value by means of filling the gauge background with the defined segment color(s) only up to the current value. The remaining part up to the Max value is left blank.
- **Show Gauge Scale:** Select this check box to show a scale.
- **No. of Major Units:** Defines the number of major units on the gauge scale.
- **No. of Minor Units:** Defines the number of minor units between each major unit on the gauge scale.
- **Show Gauge Labels:** Select this check box to show text labels on the gauge scale.
- **Label Frequency:** The density of labels can be entered in the edit box.
- **Cylinder Thickness:** The gauge is normally drawn as a solid circle or circle segment. The greater the number here, the thicker the cylinder. The value which indicates the percentage of the radius to be left unfilled must be between 0 and 99.
- **Angle Span:** The angle in degrees between the Min and Max values in the gauge. Must be a value between 45 and 360.
- **Center Angle:** The angle of the gauge's center value in relation to the clock. Must be a value between 0 and 360. 0 indicates the center at the top of the gauge (12 o'clock).
- **Popup Labels:** By selecting this check box the values of the dimension(s) and expression(s) will appear as a pop-up balloon when hovering with the cursor over data point in the chart.
- **General Tab Straight Gauge Look:**
  - **Show Gauge Indicator:** Shows the gauge value by means of a needle indicator.
  - **Indicator Style:** Specifies the style of the needle
  - **Fill Gauge to Value Only:** Shows the gauge value by means of filling the gauge background with the defined segment color(s) only up to the current value. The remaining part up to the Max value is left blank.
  - **Show Gauge Scale:** Select this check box to show a scale.
  - **No. of Major Units:** Defines the number of major units on the gauge scale.
  - **No. of Minor Units:** Defines the number of minor units between each major unit on the gauge scale.
  - **Show Gauge Labels:** Select this check box to show text labels on the gauge scale.
  - **Label Frequency:** The density of labels can be entered in the edit box.
  - **Popup Labels:** By selecting this check box the values of the dimension(s) and expression(s) will appear as a pop-up balloon when hovering with the cursor over data point in the chart.
- **General Tab Traffic Light Look:**
  - **Single Light:** Checking the box displays only one light.
  - **Indicator Style:** Specifies the style of the area surrounding the lights
  - **Fill Gauge to Value Only:** Shows the gauge value by means of filling the gauge background with the defined segment color(s) only up to the current value. The remaining part up to the Max value is left blank.
  - **Reverse Direction:** Checking the box displays the lights in reversed order.
  - **Popup Labels:** By selecting this check box the values of the dimension(s) and expression(s) will appear as a pop-up balloon when hovering with the cursor over data point in the chart.
- **General Tab LedStyle Look:**

- **Digits:** Choose how many digits there should be.
- **Digit Color:** To set the color click .
- **Popup Labels:** By selecting this check box the values of the dimension(s) and expression(s) will appear as a pop-up balloon when hovering with the cursor over data point in the chart.
- **General Tab Test Tube Look:**
  - **Test Tube Color:** To set the color click .
  - **Show Gauge Scale:** Select this check box to show a scale.
  - **No. of Major Units:** Defines the number of major units on the gauge scale.
  - **No. of Minor Units:** Defines the number of minor units between each major unit on the gauge scale.
  - **Show Gauge Labels:** Select this check box to show text labels on the gauge scale.
  - **Label Frequency:** The density of labels can be entered in the edit box.
  - **Popup Labels:** By selecting this check box the values of the dimensions and expressions will appear as a pop-up balloon when hovering with the cursor over data point in the chart.
- **General Tab Reflected Tube Look:**
  - **Show Gauge Scale:** Select this check box to show a scale.
  - **No. of Major Units:** Defines the number of major units on the gauge scale.
  - **No. of Minor Units:** Defines the number of minor units between each major unit on the gauge scale.
  - **Show Gauge Labels:** Select this check box to show text labels on the gauge scale.
  - **Label Frequency:** The density of labels can be entered in the edit box.
  - **Popup Labels:** By selecting this check box the values of the dimensions and expressions will appear as a pop-up balloon when hovering with the cursor over data point in the chart.
- **Styles:**
  - **Chart Title Style:** To set the font color of the chart title click . To set the font type click **Aa**.
  - **Scale Label:** To set the font type click **Aa**.
  - **Caption Font:** To set the caption font type click **Aa**.
  - **Active Caption:** To set the background color for the active caption click . To set the text color click .
  - **Inactive Caption:** To set the background color for the inactive caption click . To set the text color click .
  - **Use Border:** Mark this check box in order to use a border around the sheet object. Click the  to set the color of the border.

- **Border Width:** Specify a value or drag the slider to set the width of the border. The width is specified in pixels.
  - **Rounded Corners:** Click  to open the **Rounded Corners** popup.
  - **Rounded Corners** is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.
  - **Rounded Corners Popup:** Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected. Also select **Squareness** by entering a value.
- **Reference Lines:**
    - **Reference Lines:** Add a reference line by clicking .
    - **Show Label in Chart:** Displays the label next to the reference line.
    - **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
    - **X-Axis:** Select this option if the reference line should originate from the x-axis.
    - **Expression:** The value at which the reference line should be drawn. Enter an expression you wish to use as start point.
    - **Line Weight:** Specifies the weight of the reference line.
    - **Line Style:** Specifies the style of the reference line.
    - **Line Color:** Specifies the color of the reference line.
    - **Use Show Condition:** The reference line will be shown or hidden depending on a conditional expression which will be evaluated each time the chart is to be drawn. The reference line will only be hidden when the expression returns FALSE.
    - **Condition:** Enter the conditional expression. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
  - **Text:**
    - **Text in Chart:** Click  to add text in the chart.
    - **Text:** The text added in **Text in Chart** are displayed here.
    - **Tilt Angle:** Specify an angle between 0 and 360 degrees for the text. The default is 0.
    - **Horizontal Align:** Sets the horizontal alignment.
    - **On Top:** The text currently selected in the list will be forced to the foreground when drawing the chart.
    - **Text Style:**
      - To set the background color for the text click .
      - To set the font color click . To set the font type click .
    - **Size Position:** Sets the position and size of the text on the object.

## Caption

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.

The value may be entered as a calculated formula.

Click *fx* to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

## More.../Less...

This section describes **Icon Caption** properties in **More.../Less...**

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!
- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Minimize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.

- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.
- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.  
Click  to open the popup.
- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Gauge Chart Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.
- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.

- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

### 11.31 Scatter Chart - AJAX/Webview

The scatter chart presents pairs of values from two expressions. This is useful when you want to show data where each instance has two numbers, e.g. country (population and population growth).

#### Scatter Chart: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

Menu commands

| Command       | Details                                                                                                                                                                                                                                                                                                                                                                |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Properties... | Opens the <b>Properties</b> dialog for the active sheet object.                                                                                                                                                                                                                                                                                                        |
| Notes         | Allows creating and sharing notes about the current object.                                                                                                                                                                                                                                                                                                            |
| Detach        | The chart title is appended with the text "(Detached)" and the chart is no longer updated with selections made in the document (though selections may actually still be made from the chart). The command is available only if the chart is attached. By making a copy of a chart and detaching it, you may make direct comparisons between the copy and the original. |
| Attach        | Attaches a detached chart. The chart becomes dynamically linked to the data. The command is available only if the chart is detached.                                                                                                                                                                                                                                   |

| Command              | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Set Reference        | This option sets a chart reference, such as a fixed plot of the chart with the current selections. When further selections are made in the document the reference plot remains, dimmed in the background. Chart axes will be adjusted to always include the maximum of the background data set and the current data set. The current data set is always plotted on top of the reference plot. Some portions of the reference plot may be obscured by the current data set plot. The display of reference chart plots is only possible in some chart types, such as bar charts, line charts, combo charts, radar charts, scatter charts, grid charts and gauge charts with needles. It is not possible to set a reference for a chart that contains a drill-down or a cyclic group. The reference will be lost when closing the document or when reloading data. The maximum number of objects that can be included when using the <b>Set Reference</b> option is 500. |
| Clear Reference      | This command is replaced with the <b>Set Reference</b> command when a reference is set. By choosing it the previously set reference will be cleared and the chart will revert to normal plot mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Clear All Selections | Clears all the current selections in the active sheet object. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Copy                 | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Print...             | Opens the selected sheet object(s) in tabular format in another browser window.<br><br>Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Send to Excel        | Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Export...            | Opens the <b>Save as</b> dialog where path, file name and (table) file type for the exported data content can be specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Fast Change          | Makes it possible to change the current chart into another chart type. Clicking on the  icon in the object caption (if shown) produces the same result. Only available if <b>Fast Type Change in Chart</b> has been enabled on the <b>Caption</b> tab of the <b>Properties</b> dialog.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Minimize             | Iconizes the object. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if minimizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Command  | Details                                                                                                                                                                                                                                                                                                                                                                                 |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Restore  | Restores a minimized or maximized object to its previous size and location. Double-clicking the icon of a minimized object or clicking the  icon in the object caption (if shown) of a maximized object produces the same result. This command is available only for minimized or maximized objects. |
| Maximize | Enlarges the object to fill the sheet. Clicking on the <input type="checkbox"/> icon in the object caption (if shown) produces the same result. This command is available only if maximizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                                                            |
| Remove   | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                                                                             |

## Scatter Chart Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

### Dimensions

Choose dimensions in the drop-down list. To add a dimension, click . Select a dimension in the drop-down. Use the  icon to move items in the list. The  icon removes items from the list. For more settings, click the **More...** button.

### Dimension

- **Enable:** Marking this check box will enable the selected dimension. If the box is not marked, the dimension will not be used at all.
- **Conditional:** Marking this check box hides or shows the dimension dynamically, depending on the value of a condition expression entered, by clicking the *fx* button in the edit box below.
- **Dimension:** Displays the currently selected dimension.
- **Show Label:** Mark this check box to show a dimension label (the field name) on the x-axis.
- **Suppress Null Values:** If this check box is marked, the field selected as **Dimension** above will not be displayed in the chart if its value is NULL.
- **Show All Values:** Mark this check box to show all the dimension field values in the chart, including logically excluded values.
- **Show Axis Legend:** Mark this check box to show legend (names of field values) on the x-axis for the selected dimension field.
- **Limit Axis Label Characters:** Mark this check box to limit the length of the dimension value strings to be shown on axes and in the chart legend. Specify the number of characters in the input field, or drag the slider to the desired value. Truncated values will be followed by ... in the chart. This option can be used independently to the other options in this group.
- **Trellis Setting First Dimension:** Marking this check box will enable the trellis chart, where an array of charts that are based on the chart's first dimension are displayed.

- **Fixed Number of Columns:** Enter the number of columns you want the trellis chart to display. Specify the number of columns in the input field, or drag the slider to the desired value.
- **Fixed Number of Rows:** Enter the number of rows you want the trellis chart to display. Specify the number of rows in the input field, or drag the slider to the desired value.
- **Second Dimension:** Enables the second dimension in the trellis chart. If a secondary dimension is used, the first dimension values will be displayed as columns in the trellis matrix, whereas the secondary dimension values will be displayed as rows in the trellis matrix.

## Sort

Sets the sort order of the values in the sheet object. Some sort options may not be available for all sheet objects.

If more than one sort order is specified, the sort order will be state, expression, frequency, numeric, text, load order. **State** refers to the logical state (selected, optional, or excluded).

- **Primary Sort: Y-Value:** Sets whether the dimension values should be sorted according to the numeric value of the y-axis. This option is not available for calculated dimensions. **Frequency:** Sorts the field values by frequency (number of concurrences in the table). **Numeric Value:** Sorts the field values by their numeric values. **Text:** Sorts the field values in alphabetical order. **Load Order:** Sorts the field values by the initial load order.
- **Secondary Sort: Frequency:** Sorts the field values by frequency (number of concurrences in the table).  
**Numeric Value:** Sorts the field values by their numeric values.  
**Text:** Sorts the field values in alphabetical order.  
**Load Order:** Sorts the field values by the initial load order.
- **Sort by Expression:** Sorts the field values according to the expression entered. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Keep Selected on Top:** Enable this to keep the selected values on top.

## Limits

- **Restrict which values are displayed using the first expression:** These properties are used to determine how many dimension values are displayed in the chart, according to settings made below.
- **Show only:** Select this option if you want to show the **First**, **Largest** or **Smallest** x number of values. If this option is set to 5, there will be five values displayed. If the dimension has **Show Others** enabled, the Others segment will take up one of the five display slots. The **First** option will return the rows based on the options selected on the **Sort** tab of the property dialog. If the chart is a Straight Table, the rows will be returned based on the primary sort at the time. In other words, a user can change the values display by double-clicking on any column header and making that column the primary sort. The **Largest** option returns the rows in descending order based on the first expression in the chart. When used in a Straight Table, the dimension values shown will remain consistent while interactively sorting the expressions. The dimensions values will (may) change when the order of the expressions is changed. The **Smallest** option returns the rows in ascending order based on the first expression in the chart. When used in a Straight Table, the dimension values shown will remain consistent while interactively sorting the expressions. The dimensions values will (may) change when the order of the expressions is changed. Enter the number of values to display. The

value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog. Select **Include Boundary Values** to include the dimension value that contains the comparison value.

- **Show only values that are:** Select this option to display all dimensions values that meet the specified condition for this option. Select to display values based on a percentage of the total, or on an exact amount. The **relative to the total** option enables a relative mode which is similar to the **Relative** option on the **Expressions** tab of the property dialog. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Show only values that accumulate to:** When this option is selected, all rows up to the current row are accumulated, and the result is compared to the value set in the option. The **relative to the total** option enables a relative mode which is similar to the **Relative** option on the **Expressions** tab of the property dialog, and compares the accumulated values (based on first, largest or smallest values) to the overall total. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Show Others:** Enabling this option will produce an **Others** segment in the chart. All dimension values that do not meet the comparison criteria for the display restrictions will be grouped into the **Others** segment. If there are dimensions after the selected dimension, **Collapse Inner Dimensions** will control whether individual values for the subsequent / inner dimensions display on the chart. In the **Label** field, enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text.
  - The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
  - If there are dimensions after the selected dimension, **Collapse Inner Dimensions** will control whether individual values for the subsequent / inner dimensions display on the chart.
- **Show Total:** The chart will display a total for the selected dimension when this option is enabled. This total behaves differently than the expression total, which is still configured on the **Expressions** tab of the property dialog. **Label:** Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Global Grouping Mode:** The option only applies to inner dimensions. When this option is enabled the restrictions will be calculated on the selected dimension only. All previous dimensions will be ignored. If this is disabled, the restrictions are calculated based on all preceding dimensions.

## Axis

- **Show Axis:** Check this box to show the axis.
- **Axis Width:** Enter the width of the axis and its tick marks, or drag the slider to the desired value.
- **Major Label:** Select **Horizontal**, **Vertical** or **Tilted** display of the major labels.
- **Minor Label:** Select **Horizontal**, **Vertical** or **Tilted** display of the minor labels.
- **Show Grid:** Check this box to show a grid in the chart originating from the tick marks of the x-axis. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Show Minor Grid:** Check this box to show minor lines in-between the grid lines. Only available if **Show Grid** is selected. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.

- **Stagger Labels:** Select this option to stagger x-axis labels when they become too many to show side by side.
- **Reverse Stagger:** X-axis labels are normally staggered bottom-up from left to right. When marking this check box, the stagger will be reversed to top-down.
- **Continuous X:** Sets the x-axis to be continuous, i.e. it will be interpreted numerically and shown with numerically correct intervals.
- **Force 0:** Fixes the lower edge of the chart to zero on the y-axis. This option is not available when a logarithmic axis is used.
- **Label Along Axis:** Check this box to change the position of the x-axis label.
- **Static Min:** Sets a fixed minimum value for the axis. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Max:** Sets a fixed maximum value for the axis. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Step:** Sets a fixed interval for tick marks on the axis. If this setting results in more than 100 tick marks, the value used will be modified. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Backcast:** By entering an integer in the edit field, you force the x-axis to be extended to the left of the actual data points plotted. This is useful when using trend lines. The backcast line will be dotted. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Forecast:** By entering an integer in the edit field, you force the x-axis to be extended to the right of the actual data points plotted. This is useful when using trendlines. The forecast line will be dotted. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

## Expressions

Choose expressions in the drop-down list. To add an expression, click . Select an expression from the drop-down. Use the  icon to move items in the list. The  icon removes items from the list. For more information click the **More...** button.

### Expression

- **Enable:** Marking this check box will enable the selected expression. If the box is not marked, the expression will not be used at all.
- **Conditional:** Marking this check box hides or shows the expression dynamically, depending on the value of a condition expression entered, by clicking the *fx* button in the edit box below.
- **Label:** The label of the expression. Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Expression:** Displays the currently selected expression.
- **Comment:** Enter a comment to describe the purpose and function of the expression. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Invisible:** Hides the expression.

- **Show in Percent (Relative):** The chart shows the result in percent instead of absolute numbers.
- **Accumulate Expression:**

Check this box to accumulate expressions. Click  to open the popup.

- **Accumulation Popup:** Select one of the options to decide whether the values in the sheet object should be accumulated or not.
  - **Accumulate:** In an accumulated chart, each y-value is added to the y-value of the following x-value.
  - **No Accumulation:** The y-values of the selected chart expression will not be accumulated.
  - **Full Accumulation:** Each y-value accumulating all previous y-values of the expression. Full accumulation does not work if the chart trellis is enabled.
  - **Accumulation Steps:** Enter a number in the box or drag the slider to set the number of y-values in the expression to be accumulated.
- **Use Trendlines:**

Check this box to use trendlines. Click  to open the popup.

**Trendline Popup:** Choose one of the following Trendline options:

- **Average:** The average is plotted as a straight line.
  - **Linear:** A linear regression line is plotted.
  - **Polynomial of 2nd degree:** A polynomial trend line of the second degree is plotted.
  - **Polynomial of 3rd degree:** A polynomial trend line of the third degree is plotted.
  - **Polynomial of 4th degree:** A polynomial trend line of the fourth degree is plotted.
  - **Exponential:** An exponential trend line is plotted.  
For each option, it is possible to check the **Show Equation** box and the **Show R<sup>2</sup>** box.
    - **Show Equation:** If this check box is marked for a specific expression, the expression's trend lines will be complemented by the trend line equation expressed as text in the chart.
    - **Show R<sup>2</sup>:** If this check box is marked for a specific expression, the expression's trend lines will be complemented by the coefficient of determination expressed as text in the chart.
- 
- **Show in Legend:** When several expressions are used, this option displays a legend showing the expressions and their corresponding colors next to the chart.
  - **Value Display Settings:**
    - **Show Values on Datapoints:** Mark this check box to display the result of the expression as text on top of the data points.

- **Text as Popup:** Mark this check box to have the result of the expression shown in the popup balloon messages appearing when hovering over a data point in a chart in the layout. This option can be used with or without any of the other display options. It is thus possible to have an expression that does not appear in the chart itself, but only in hover popups.
- **Text on Axis:** Plots the result of the expression at each x-axis value, the axis and the axis labels.
- **Attribute Expression Styles:**
  - **Background Color:** Define an attribute expression for calculating the basic plot color of the data point. The expression used should return a valid color representation (a number representing the Red, Green and Blue components as defined in Visual Basic) which is typically achieved by using one of the special chart color functions. If the result of the expression is not a valid color representation, black will be used.
  - **Number Format Tab:** Each field has a default number format which can be set in the Document Properties: Number page. It is however possible to use a separate number format for an individual sheet object. This property page applies to the active object and contains the following controls for formatting values:
    - **Number Format:** Choose a number format from the alternatives below.
    - **Default:** Both numbers and text. Numbers are shown in original format.
    - **Number:** Shows numeric values with the number of digits set in the **Precision** field.
    - **Integer:** Shows numeric values as integers.
    - **Fixed to:** Shows numeric values as decimal values with the number of decimal digits set in the **Decimals** field.
    - **Money:** Shows values in the format set in the **Format Pattern** field. The default format is the Windows Currency setting.
    - **Date:** Shows values that can be interpreted as dates in the format set in the **Format Pattern** field.
    - **Time:** Shows values that can be interpreted as time in the format set in the **Format Pattern** field.
    - **Timestamp:** Shows values that can be interpreted as date + time in the format set in the **Format Pattern** field.
    - **Interval:** Shows time as sequential time increments (e.g. format = mm shows the value as the number of minutes since calendar start (1899:12:30:24:00)).
    - **Format Pattern:** The format code that further specifies the display format of the field. **ISO** sets the format to the ISO standard. Only valid for **Date**, **Time**, **Timestamp** and **Interval**. **Sys** sets the format to the system settings.
    - **Precision:** The number of digits that will be displayed.
    - **Decimals:** Sets the number of decimals included.
    - **Decimals Separator:** Sets the symbol for decimal separators.
    - **Thousand Separator:** Sets the symbol for thousand separators.
    - **In Percent:** Shows formatting in percentage instead of absolute numbers. The

setting is only available for **Number**, **Integer** and **Fixed to**.

- **Preview:** Shows a preview of the number format specified above.

### Axis

- **Show Axis:** Check this box to show the axis.
- **Axis Width:** Enter the width of the axis and its tick marks, or drag the slider to the desired value.
- **Position:** Choose **Left** or **Right** position. If **Split Axis** was selected, choose **Top** or **Bottom** position.
- **Show Grid:** Check this box to show a grid in the chart originating from the tick marks of the x-axis. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Show Minor Grid:** Check this box to show minor lines in-between the grid lines. Only available if **Show Grid** is selected. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Log Scale:** If this box is checked, the scale will be logarithmic.
- **Force 0:** Fixes the lower edge of the chart to zero on the y-axis. This option is not available when a logarithmic axis is used.
- **Static Min:** Sets a fixed minimum value for the axis. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Max:** Sets a fixed maximum value for the axis. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Step:** Sets a fixed interval for tick marks on the axis. If this setting results in more than 100 tick marks, the value used will be modified. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Center:** Sets a fixed value on the axis which will be positioned in the center of the plot area. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

### Show Title

By default, the label of the first expression defined is set as chart title. Clear the check box if you do not wish to have a chart title. The title may be defined as a calculated formula for dynamic update. Click *fx* to open the **Edit Expression** dialog.

### More.../Less...

Click this button to expand/collapse the foldout that contains additional tabs. Depending on if the **Dimensions** or **Expressions** field is active, different tabs are displayed.

## Scatter Chart Properties: Presentation

This section describes **Scatter Chart** properties.

### Look

Select one of the available looks in the drop-down.

### Symbol Size

Determines the size of symbols, if a symbol representation is specified.

## Max Bubble Size

Sets the size of the largest bubble in the chart. Available only for some looks and if **Autosize Symbols** is deselected.

## Show Legend

Displays the legend in the chart. Click  to open the popup.

## Legend Settings Popup

- **Legend Style:** Sets the legend style.
- **Vertical:** Sets the vertical alignment of the legend.
- **Line Spacing:** Specifies the distance between items in the legend.
- **Reverse Order:** To reverse the sort order of the legend mark this check box.
- **Wrap Cell Text:** If this check box is marked, the text of the legend items will be wrapped in two or more lines.

## Background

Sets the background of the chart. The following options are available:

- **Color:** Click  to select a color.
- **Image:** Click  to change the image.
- **Dynamic Image:** Enter a calculated expression to show dynamic background images that change with the selection.

## Plot Area Background

Sets the background of the plot area. The following options are available:

- **Color:** The plot area will have a colored background. Click  to select a color.
- **Image:** The plot area will have an image background. Click  to change the image.
- **Dynamic Image:** Enter a calculated expression to show dynamic background images that change with the selection.

## Plot Area Style

This control can be used to change the appearance of the plot area background. The following options are available:

- **Frame:** A frame is drawn around the plot area.
- **Shadow:** This options gives a shadow effect on the plot area background.
- **Minimal:** The plot area background is removed.

## Background Transparency

Enter a value in the box or drag the slider to set transparency for the chart.

## More.../Less...

This section describes **More.../Less...** properties.

### General

- **Labels on Datapoints:** Check this box to display labels.
- **Max Labels Shown:** In this box, specify an upper limit for how many data points to show values for in the chart. If no limit is specified, values will be shown for all data points, which may affect the readability of the chart.
- **Horizontal Position:** Select **Left**, **Centered** or **Right** for horizontal orientation of labels on datapoints.
- **Vertical Position:** Select **Above**, **Centered** or **Below** for vertical orientation of labels on datapoints.
- **Show X Label:** Displays a label at the end of the x-axis.
- **Show Y Label:** Displays a label at the end of the y-axis.
- **Suppress Zero-Values:** If this check box is marked, all combinations of the dimension fields returning zero or null from all expressions will be disregarded in the calculation. This option is selected by default.
- **Suppress Missing:** If this check box is marked, all combinations of the dimension fields associated with only null values in all fields in all expressions will be disregarded in the calculation. This option is selected by default. Turning it off can be useful only in special cases, e.g. if null values is to be counted in a chart.
- **Popup Labels:** By selecting this check box the values of the dimension(s) and expression(s) will appear as a pop-up balloon when hovering with the cursor over data point in the chart.
- **Highlight:** If this check box is marked hovering with the mouse over a line or symbol in it will result in the line or symbol being highlighted for better overview. The highlighting applies also in the legend where applicable.
- **Show Arrows:** Display options for arrows on connecting lines Arrows will be directed between scatter points in the sequential order defined by the sort order of the second field dimension. Check this alternative to have arrow heads displayed on the connecting lines.
- **Arrow Size:** The size of the arrow heads.
- **Arrow style:** Select from several styles from the drop-down list.
- **Calculation Conditions:** The expression entered here sets a condition to be fulfilled for the chart to be calculated. If the condition is not fulfilled, the text 'Calculation condition unfulfilled' will be displayed in the chart. displayed at any one time. Enter the maximum number of values. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

### Styles

- **Legend:** To set the color of the legend click . To set the font color click . To set the font type click .
- **Chart Title Style:** To set the font color of the chart title click . To set the font type click .

- **Caption Font:** To set the caption font type click .
- **Active Caption:** To set the background color for the active caption click . To set the text color click .
- **Inactive Caption:** To set the background color for the inactive caption click . To set the text color click .
- **Use Border:** Mark this check box in order to use a border around the sheet object. Click the  to set the color of the border.
- **Border Width:** Specify a value or drag the slider to set the width of the border. The width is specified in pixels.
- **Rounded Corners:** Click  to open the **Rounded Corners** popup.
  - **Rounded Corners Popup:** Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected. Also select **Squareness** by entering a value.

***Rounded Corners** is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.*

- **Trendline Width:** Specify the width of the trendline.
  - **Reference Lines:**
    - **Reference Lines:** Add a reference line by clicking .
    - **Show Label in Chart:** Displays the label next to the reference line.
    - **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
    - **X-Axis:** Select this option if the reference line should originate from the x-axis.
    - **Expression:** The value at which the reference line should be drawn. Enter an expression you wish to use as start point.
    - **Line Weight:** Specifies the weight of the reference line.
    - **Line Style:** Specifies the style of the reference line.
    - **Line Color:** Specifies the color of the reference line.
    - **Use Show Condition:** The reference line will be shown or hidden depending on a conditional expression which will be evaluated each time the chart is to be drawn. The reference line will only be hidden when the expression returns FALSE.
    - **Condition:** Enter the conditional expression. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.

- **Text:**
  - **Text in Chart:** Click  to add text in the chart.
  - **Text:** The text added in **Text in Chart** are displayed here.
  - **Tilt Angle:** Specify an angle between 0 and 360 degrees for the text. The default is 0.
  - **Horizontal Align:** Sets the horizontal alignment.
  - **On Top:** The text currently selected in the list will be forced to the foreground when drawing the chart.
  - **Text Style:**
    - To set the background color for the text click .
    - To set the font color click . To set the font type click .
  - **Size Position:** Sets the position and size of the text on the object.

## Scatter Chart Properties: Caption

This section describes **Scatter Chart** properties.

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.  
The value may be entered as a calculated formula.

Click  to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

## More.../Less...

This section describes **More.../Less...** properties.

### Icons in Caption

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!

- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!
- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Maximize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.
- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.  
Click  to open the popup.
- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Scatter Chart Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.

- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.
- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.32 Grid Chart - AJAX/Webview

The grid chart is similar to the scatter chart but plots dimension values on the axes and uses an expression to determine the plot symbol. A special mode makes it possible to show a third dimension in the form of small pie charts as plot symbols.

### Grid Chart: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

## Menu commands

| Command              | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Properties...        | Opens the <b>Properties</b> dialog for the active sheet object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Notes                | Allows creating and sharing notes about the current object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Detach               | The chart title is appended with the text “(Detached)” and the chart is no longer updated with selections made in the document (though selections may actually still be made from the chart). The command is available only if the chart is attached. By making a copy of a chart and detaching it, you may make direct comparisons between the copy and the original.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Attach               | Attaches a detached chart. The chart becomes dynamically linked to the data. The command is available only if the chart is detached.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Set Reference        | This option sets a chart reference, such as a fixed plot of the chart with the current selections. When further selections are made in the document the reference plot remains, dimmed in the background. Chart axes will be adjusted to always include the maximum of the background data set and the current data set. The current data set is always plotted on top of the reference plot. Some portions of the reference plot may be obscured by the current data set plot. The display of reference chart plots is only possible in some chart types, such as bar charts, line charts, combo charts, radar charts, scatter charts, grid charts and gauge charts with needles. It is not possible to set a reference for a chart that contains a drill-down or a cyclic group. The reference will be lost when closing the document or when reloading data. The maximum number of objects that can be included when using the <b>Set Reference</b> option is 500. |
| Clear Reference      | This command is replaced with the <b>Set Reference</b> command when a reference is set. By choosing it the previously set reference will be cleared and the chart will revert to normal plot mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Clear All Selections | Clears all the current selections in the active sheet object. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Copy                 | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Print...             | Opens the selected sheet object(s) in tabular format in another browser window.<br><br>Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Send to Excel        | Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Export...            | Opens the <b>Save as</b> dialog where path, file name and (table) file type for the exported data content can be specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Command     | Details                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fast Change | Makes it possible to change the current chart into another chart type. Clicking on the  icon in the object caption (if shown) produces the same result. Only available if <b>Fast Type Change in Chart</b> has been enabled on the <b>Caption</b> tab of the <b>Properties</b> dialog.                 |
| Minimize    | Iconizes the object. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if minimizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                     |
| Restore     | Restores a minimized or maximized object to its previous size and location. Double-clicking the icon of a minimized object or clicking the  icon in the object caption (if shown) of a maximized object produces the same result. This command is available only for minimized or maximized objects. |
| Maximize    | Enlarges the object to fill the sheet. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if maximizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                  |
| Remove      | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                                                                             |

## Grid Chart Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

## Grid Chart Properties

This section describes **Grid Chart Properties**.

### Dimensions

Choose dimensions in the drop-down list. To add a dimension, click . Select a dimension in the drop-down. Use the  icon to move items in the list. The  icon removes items from the list. For more settings, click the **More...** button.

### Dimension Tab

- **Enable Conditional:** Marking this check box hides or shows the dimension dynamically, depending on the value of a condition expression entered, by clicking the  button in the edit box below.
- **Dimension:** Displays the currently selected dimension.
- **Show Label:** Mark this check box to show a dimension label (the field name) on the x-axis.
- **Suppress Null Values:** If this check box is marked, the field selected as **Dimension** above will not be displayed in the chart if its value is NULL.
- **Show All Values:** Mark this check box to show all the dimension field values in the chart, including logically excluded values.

- **Show Axis Labels:** Mark this check box to show legend (names of field values) on the x-axis for the selected dimension field.
- **Limit Axis Label Characters:** Mark this check box to limit the length of the dimension value strings to be shown on axes and in the chart legend. Specify the number of characters in the input field, or drag the slider to the desired value. Truncated values will be followed by ... in the chart. This option can be used independently to the other options in this group.
- **Trellis Setting First Dimension:** Marking this check box will enable the trellis chart, where an array of charts that are based on the chart's first dimension are displayed.
- **Fixed Number of Columns:** Enter the number of columns you want the trellis chart to display. Specify the number of columns in the input field, or drag the slider to the desired value.
- **Fixed Number of Rows:** Enter the number of rows you want the trellis chart to display. Specify the number of rows in the input field, or drag the slider to the desired value.
- **Second Dimension:** Enables the second dimension in the trellis chart. If a secondary dimension is used, the first dimension values will be displayed as columns in the trellis matrix, whereas the secondary dimension values will be displayed as rows in the trellis matrix.

### Sort Tab

Sets the sort order of the values in the sheet object. Some sort options may not be available for all sheet objects.

If more than one sort order is specified, the sort order will be state, expression, frequency, numeric, text, load order. **State** refers to the logical state (selected, optional, or excluded).

- **Primary Sort:**
  - **Y-Value:** Sets whether the dimension values should be sorted according to the numeric value of the y-axis. This option is not available for calculated dimensions.
  - **Frequency:** Sorts the field values by frequency (number of concurrences in the table).
  - **Numeric Value:** Sorts the field values by their numeric values.
  - **Text:** Sorts the field values in alphabetical order.
  - **Load Order:** Sorts the field values by the initial load order.
- **Secondary Sort:**
  - **Frequency:** Sorts the field values by frequency (number of concurrences in the table).
  - **Numeric Value:** Sorts the field values by their numeric values.
  - **Text:** Sorts the field values in alphabetical order.
  - **Load Order:** Sorts the field values by the initial load order.
- **Sort by Expression:**
  - Sorts the field values according to the expression entered.
  - The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Keep Selected on Top:** Enable this to keep the selected values on top.

### Limits

- **Restrict which values are displayed using the first expression:** These properties are used to determine how many dimension values are displayed in the chart, according to settings made

below.

- **Show only:**

Select this option if you want to show the **First**, **Largest** or **Smallest** x number of values. If this option is set to 5, there will be five values displayed. If the dimension has **Show Others** enabled, the Others segment will take up one of the five display slots.

- The **First** option will return the rows based on the options selected on the **Sort** tab of the property dialog. If the chart is a Straight Table, the rows will be returned based on the primary sort at the time. In other words, a user can change the values display by double-clicking on any column header and making that column the primary sort.
- The **Largest** option returns the rows in descending order based on the first expression in the chart. When used in a Straight Table, the dimension values shown will remain consistent while interactively sorting the expressions. The dimensions values will (may) change when the order of the expressions is changed.
- The **Smallest** option returns the rows in ascending order based on the first expression in the chart. When used in a Straight Table, the dimension values shown will remain consistent while interactively sorting the expressions. The dimensions values will (may) change when the order of the expressions is changed.
- Enter the number of values to display.
- The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- Select **Include Boundary Values** to include the dimension value that contains the comparison value.
- **Show only values that are:** Select this option to display all dimensions values that meet the specified condition for this option.
  - Select to display values based on a percentage of the total, or on an exact amount.
  - The **relative to the total** option enables a relative mode which is similar to the **Relative** option on the **Expressions** tab of the property dialog.
  - The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Show only values that accumulate to:** When this option is selected, all rows up to the current row are accumulated, and the result is compared to the value set in the option.
  - The **relative to the total** option enables a relative mode which is similar to the **Relative** option on the **Expressions** tab of the property dialog, and compares the accumulated values (based on first, largest or smallest values) to the overall total.
  - The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Show Others:** Enabling this option will produce an **Others** segment in the chart. All dimension values that do not meet the comparison criteria for the display restrictions will be grouped into the **Others** segment. If there are dimensions after the selected dimension, **Collapse Inner Dimensions** will control whether individual values for the subsequent / inner dimensions display on the chart. In the **Label** field, enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text.  
The value may be entered as a calculated formula. Click

*fx* to open the **Edit Expression** dialog. If there are dimensions after the selected dimension, **Collapse Inner Dimensions** will control whether individual values for the subsequent / inner dimensions display on the chart.

- **Show Total:** The chart will display a total for the selected dimension when this option is enabled. This total behaves differently than the expression total, which is still configured on the **Expressions** tab of the property dialog. **Label:** Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Use Global Grouping Mode:** The option only applies to inner dimensions. When this option is enabled the restrictions will be calculated on the selected dimension only. All previous dimensions will be ignored. If this is disabled, the restrictions are calculated based on all preceding dimensions.

## Expressions

Choose expressions in the drop-down list. To add an expression, click . Select an expression from the drop-down. Use the  icon to move items in the list. The  icon removes items from the list. For more information click the **More...** button.

## Expression

This section describes **Expression** properties.

### Enable

Marking this check box will enable the selected expression. If the box is not marked, the expression will not be used at all.

### Conditional

Marking this check box hides or shows the expression dynamically, depending on the value of a condition expression entered, by clicking the *fx* button in the edit box below.

### Label

The label of the expression. Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

### Expression

Displays the currently selected expression.

### Comment

Enter a comment to describe the purpose and function of the expression. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

### Invisible

Hides the expression.

### Show in Percent (Relative)

The chart shows the result in percent instead of absolute numbers.

### Show in Legend

When several expressions are used, this option displays a legend showing the expressions and their corresponding colors next to the chart.

### Value Display Settings

Check this box to define how to display values. Click  to open the popup.

### Value Display Settings Popup

- **Text as Popup:** Mark this check box to have the result of the expression shown in the popup balloon messages appearing when hovering over a data point in a chart in the layout. This option can be used with or without any of the other display options. It is thus possible to have an expression that does not appear in the chart itself, but only in hover popups.
- **Attribute Expression Styles:**
  - **Background Color:** Define an attribute expression for calculating the basic plot color of the data point. The expression used should return a valid color representation (a number representing the Red, Green and Blue components as defined in Visual Basic) which is typically achieved by using one of the special chart color functions. If the result of the expression is not a valid color representation, black will be used.
  - **Number Format Tab:** Each field has a default number format which can be set in the Document Properties: Number page. It is however possible to use a separate number format for an individual sheet object. This property page applies to the active object and contains the following controls for formatting values:
    - **Number Format:** Choose a number format from the alternatives below.
    - **Default:** Both numbers and text. Numbers are shown in original format.
    - **Number:** Shows numeric values with the number of digits set in the **Precision** field.
    - **Integer:** Shows numeric values as integers.
    - **Fixed to:** Shows numeric values as decimal values with the number of decimal digits set in the **Decimals** field.
    - **Money:** Shows values in the format set in the **Format Pattern** field. The default format is the Windows Currency setting.
    - **Date:** Shows values that can be interpreted as dates in the format set in the **Format Pattern** field.
    - **Time:** Shows values that can be interpreted as time in the format set in the **Format Pattern** field.
    - **Timestamp:** Shows values that can be interpreted as date + time in the format set in the **Format Pattern** field.
    - **Interval:** Shows time as sequential time increments (e.g. format = mm shows the value as the number of minutes since calendar start (1899:12:30:24:00)).

- **Format Pattern:** The format code that further specifies the display format of the field. **ISO** sets the format to the ISO standard. Only valid for **Date**, **Time**, **Timestamp** and **Interval**. **Sys** sets the format to the system settings.
- **Precision:** The number of digits that will be displayed.
- **Decimals:** Sets the number of decimals included.
- **Decimals Separator:** Sets the symbol for decimal separators.
- **Thousand Separator:** Sets the symbol for thousand separators.
- **In Percent:** Shows formatting in percentage instead of absolute numbers. The setting is only available for **Number**, **Integer** and **Fixed to**.
- **Preview:** Shows a preview of the number format specified above.

### Show Title

By default, the label of the first expression defined is set as chart title. Clear the check box if you do not wish to have a chart title. The title may be defined as a calculated formula for dynamic update. Click *fx* to open the **Edit Expression** dialog.

### More.../Less...

Click this button to expand/collapse the foldout that contains additional tabs. Depending on if the **Dimensions** or **Expressions** field is active, different tabs are displayed.

## Grid Chart Properties: Presentation

### Presentation Properties

This section describes **Presentation** properties.

#### Look

Select one of the available looks in the drop-down.

#### Autosize Symbols

Adjusts the maximum bubble size to the number of values in the chart.

#### Symbol Size

Determines the size of symbols, if a symbol representation is specified.

#### Max Bubble Size

Sets the size of the largest bubble in the chart. Available only for some looks and if **Autosize Symbols** is deselected.

#### Show Legend

Displays the legend in the chart.

Click  to open the popup:

- **Legend Settings Popup:**
  - **Legend Style:** Sets the legend style.
  - **Vertical Placement:** Sets the vertical alignment of the legend.
  - **Line Spacing:** Specifies the distance between items in the legend.
  - **Reverse Order:** To reverse the sort order of the legend mark this check box.
  - **Wrap Cell Text:** Wrap the text of the legend items in two or more lines.

## Background

- Sets the background of the chart. The following options are available:
  - **Color:** Click  to select a color.
  - **Image:** Click  to change the image.
- Click  to set the background transparency. Enter a value in the box or drag the slider to set transparency for the chart
- **Dynamic Image:** Click  to set the background transparency and dynamic image.
  - Enter a value in the box or drag the slider to set transparency for the chart.
  - Enter a calculated expression to show dynamic background images that change with the selection.

## Plot Area Background

Sets the background of the plot area.

The following options are available:

- **Color:** The plot area will have a colored background. Click  to set the plot area style and the background transparency. Click  to select a color.
- **Image:** The plot area will have an image background. Click  to set the background transparency. Click  to change the image.
- **Dynamic Image:** Click  to set the background transparency and dynamic image. Enter a value in the box or drag the slider to set transparency for the chart. Enter a calculated expression to show dynamic background images that change with the selection.

## Plot Area Style

This control can be used to change the appearance of the plot area background.

- The following options are available:
  - **Frame:** A frame is drawn around the plot area.
  - **Shadow:** This options gives a shadow effect on the plot area background.
  - **Minimal:** The plot area background is removed.

## More.../Less...

This section describes several elements in the **More.../Less...** properties.

- **General:**
  - **Labels on Datapoints:** Check this box to display labels
  - **Max Values Shown:** In this box, specify an upper limit for how many data points to show values for in the chart. If no limit is specified, values will be shown for all data points, which may affect the readability of the chart.
  - **Horizontal Position:** Select **Left**, **Centered** or **Right** for horizontal orientation of labels on datapoints.
  - **Vertical Position:** Select **Above**, **Centered** or **Below** for vertical orientation of labels on datapoints.
  - **Show X Label:** Displays a label at the end of the x-axis.
  - **Show Y Label:** Displays a label at the end of the y-axis.
  - **Suppress Zero-Values:**
    - If this check box is marked, all combinations of the dimension fields returning zero or null from all expressions will be disregarded in the calculation.
    - This option is selected by default.
  - **Suppress Missing:**
    - If this check box is marked, all combinations of the dimension fields associated with only null values in all fields in all expressions will be disregarded in the calculation.
    - This option is selected by default. Turning it off can be useful only in special cases, e.g. if null values is to be counted in a chart.
  - **Popup Labels:** By selecting this check box the values of the dimension(s) and expression(s) will appear as a pop-up balloon when hovering with the cursor over data point in the chart.
  - **Highlight:** If this check box is marked hovering with the mouse over a line or symbol in it will result in the line or symbol being highlighted for better overview. The highlighting applies also in the legend where applicable.
  - **Show Arrows:** Display options for arrows on connecting lines Arrows will be directed between scatter points in the sequential order defined by the sort order of the second field dimension. Check this alternative to have arrow heads displayed on the connecting lines.
  - **Arrow Size:** The size of the arrow heads.
  - **Arrow Style:** Select from several styles from the drop-down list.
  - **Calculation Conditions:** The expression entered here sets a condition to be fulfilled for the chart to be calculated. If the condition is not fulfilled, the text 'Calculation condition unfulfilled' will be displayed in the chart. displayed at any one time. Enter the maximum number of values. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
- **Styles:**
  - Legend: To set the color of the legend click . To set the font color click . To set the font type click .

- **Chart Title Style:** To set the font color of the chart title click . To set the font type click **Aa**.
- **Caption Font:** To set the caption font type click **Aa**.
- **Active Caption:** To set the background color for the active caption click . To set the text color click .
- **Inactive Caption:** To set the background color for the inactive caption click . To set the text color click .
- **Use Border:** Mark this check box in order to use a border around the sheet object. Click the  to set the color of the border.
- **Border Width:** Specify a value or drag the slider to set the width of the border. The width is specified in pixels.
- **Rounded Corners:**
  - Click  to open the **Rounded Corners** popup.

***Rounded Corners** is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.*

- **Rounded Corners Popup:**
  - Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected.
  - Select **Squareness** by enterign a value.
- **Reference Lines:**
  - **Reference Lines:** Add a reference line by clicking .
  - **Show Label in Chart:** Displays the label next to the reference line.
  - **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
  - **X-Axis:** Select this option if the reference line should originate from the x-axis.
  - **Expression:** The value at which the reference line should be drawn. Enter an expression you wish to use as start point.
  - **Line Weight:** Specifies the weight of the reference line.
  - **Line Style:** Specifies the style of the reference line.
  - **Line Color:** Specifies the color of the reference line.

- **Use Show Condition:** The reference line will be shown or hidden depending on a conditional expression which will be evaluated each time the chart is to be drawn. The reference line will only be hidden when the expression returns FALSE.
- **Condition:** Enter the conditional expression. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Text:**
  - **Text in Chart:** Click  to add text in the chart.
  - **Text:** The text added in **Text in Chart** are displayed here.
  - **Tilt Angle:** Specify an angle between 0 and 360 degrees for the text. The default is 0.
  - **Horizontal Align:** Sets the horizontal alignment.
  - **On Top:** The text currently selected in the list will be forced to the foreground when drawing the chart.
  - **Text Style:**
    - To set the background color for the text click .
    - To set the font color click . To set the font type click .
  - **Size Position:** Sets the position and size of the text on the object.

## Grid Chart Properties: Caption

This section describes **Caption** properties.

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.

The value may be entered as a calculated formula.

Click *fx* to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

## More.../Less...

This section describes the icons in **Caption** properties.

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!
- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Maximize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.
- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.  
Click  to open the popup.
- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Grid Chart Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.

- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.
- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

### 11.33 Pie Chart - AJAX/Webview

Pie charts normally show the relation between a single dimension and a single expression, but can sometimes have two dimensions.

#### Pie Chart: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

## Menu commands

| Command              | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Properties...        | Opens the <b>Properties</b> dialog for the active sheet object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Notes                | Allows creating and sharing notes about the current object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Detach               | The chart title is appended with the text "(Detached)" and the chart is no longer updated with selections made in the document (though selections may actually still be made from the chart). The command is available only if the chart is attached. By making a copy of a chart and detaching it, you may make direct comparisons between the copy and the original.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Attach               | Attaches a detached chart. The chart becomes dynamically linked to the data. The command is available only if the chart is detached.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Set Reference        | This option sets a chart reference, such as a fixed plot of the chart with the current selections. When further selections are made in the document the reference plot remains, dimmed in the background. Chart axes will be adjusted to always include the maximum of the background data set and the current data set. The current data set is always plotted on top of the reference plot. Some portions of the reference plot may be obscured by the current data set plot. The display of reference chart plots is only possible in some chart types, such as bar charts, line charts, combo charts, radar charts, scatter charts, grid charts and gauge charts with needles. It is not possible to set a reference for a chart that contains a drill-down or a cyclic group. The reference will be lost when closing the document or when reloading data. The maximum number of objects that can be included when using the <b>Set Reference</b> option is 500. |
| Clear Reference      | This command is replaced with the <b>Set Reference</b> command when a reference is set. By choosing it the previously set reference will be cleared and the chart will revert to normal plot mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Clear All Selections | Clears all the current selections in the active sheet object. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Copy                 | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Print...             | Opens the selected sheet object(s) in tabular format in another browser window.<br><br>Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Send to Excel        | Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Command     | Details                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Export...   | Opens the <b>Save as</b> dialog where path, file name and (table) file type for the exported data content can be specified.                                                                                                                                                                                                                                                             |
| Fast Change | Makes it possible to change the current chart into another chart type. Clicking on the <b>»»</b> icon in the object caption (if shown) produces the same result. Only available if <b>Fast Type Change in Chart</b> has been enabled on the <b>Caption</b> tab of the <b>Properties</b> dialog.                                                                                         |
| Minimize    | Iconizes the object. Clicking on the <b>—</b> icon in the object caption (if shown) produces the same result. This command is available only if minimizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                                                                                              |
| Restore     | Restores a minimized or maximized object to its previous size and location. Double-clicking the icon of a minimized object or clicking the  icon in the object caption (if shown) of a maximized object produces the same result. This command is available only for minimized or maximized objects. |
| Maximize    | Enlarges the object to fill the sheet. Clicking on the <input type="checkbox"/> icon in the object caption (if shown) produces the same result. This command is available only if maximizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                                                            |
| Remove      | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                                                                             |

## Pie Chart Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

## Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.

- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## Pie Chart Properties: Presentation

This section describes **Pie Chart** properties in **Presentation**.

### Look

Select one of the available looks in the drop-down.

### Show Legend

Displays the legend in the chart. Click  to open the popup.

### Legend Settings Popup

- **Legend Style:** Sets the legend style.
- **Vertical:** Sets the vertical alignment of the legend.
- **Line Spacing:** Specifies the distance between items in the legend.
- **Reverse Order:** To reverse the sort order of the legend mark this check box.
- **Wrap Cell Text:** If this check box is marked, the text of the legend items will be wrapped in two or more lines.

### Background

Sets the background of the chart. The following options are available:

## Color

The plot area will have a colored background. Click  to select a color.

## Image

The plot area will have an image background. Click  to change the image.

## Dynamic Image

Enter a calculated expression to show dynamic background images that change with the selection.

## Background Transparency

Enter a value in the box or drag the slider to set transparency for the chart. Click  to set the transparency.

## More.../Less...

This section describes several properties in **More.../Less...**

### General

- **Suppress Zero-Values:** If this check box is marked, all combinations of the dimension fields returning zero or null from all expressions will be disregarded in the calculation. This option is selected by default.
- **Suppress Missing:** If this check box is marked, all combinations of the dimension fields associated with only null values in all fields in all expressions will be disregarded in the calculation. This option is selected by default. Turning it off can be useful only in special cases, e.g. if null values is to be counted in a chart.
- **Popup Labels:** By selecting this check box the values of the dimensions and expressions will appear as a pop-up balloon when hovering with the cursor over data point in the chart.
- **Highlight:** This option is not supported for AJAX/Webview.
- **Calculation Conditions:** The expression entered here sets a condition to be fulfilled for the chart to be calculated. If the condition is not fulfilled, the text 'Calculation condition unfulfilled' will be displayed in the chart. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.

### Styles

- **Legend:** To set the color of the legend click . To set the font color click . To set the font type click .
- **Caption Font:** To set the caption font type click .
- **Chart Title Style:** To set the font color of the chart title click . To set the font type click .

- **Active Caption:** To set the background color for the active caption click . To set the text color click .
- **Inactive Caption:** To set the background color for the inactive caption click . To set the text color click .
- **Use Border:** Mark this check box in order to use a border around the sheet object. Click the  to set the color of the border.
- **Border Width:** Specify a value or drag the slider to set the width of the border. The width is specified in pixels.
- **Rounded Corners:** Click  to open the **Rounded Corners** popup.

*Rounded Corners is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.*

- Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected. Also select **Squareness** by entering a value.

## Text

This section describes properties in **Text**.

### Text in Chart

Click  to add text in the chart.

### Text

The text added in **Text in Chart** are displayed here.

### Tilt Angle

Specify an angle between 0 and 360 degrees for the text. The default is 0.

### Horizontal Align

Sets the horizontal alignment.

### On top

The text currently selected in the list will be forced to the foreground when drawing the chart.

### Text Style

To set the background color for the text click .

To set the font color click . To set the font type click .

### Size Position

Sets the position and size of the text on the object.

## Pie Chart Properties: Caption

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.

The value may be entered as a calculated formula.

Click *fx* to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

## Icons in Caption Properties

This section describes the **More.../Less...** in **Icons in Caption** property.

### Menu

Opens the object menu

### Clear

Clears all the current selections in the active sheet object.

### Print

Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!

### Copy Data

Copies the field values in the sheet object. Some clients may not handle this setting!

### Copy Image to Clipboard

Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!

### Send to Excel

Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 97 or later must be installed on the computer. Some clients may not handle this setting!

### Allow Minimize

When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.

### Auto Minimize

This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.

### Allow Maximize

When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.

### Help Text

Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.

### Fast Type Change in Caption

Check this box to use Fast Type Change in Caption.

- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Pie Chart Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.

- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.
- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click  , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.34 Funnel Chart - AJAX/WebView

The funnel chart is typically used for showing data in flows and processes. From a display standpoint it is related to the pie chart. The chart may be shown with either segment height/width or segment area proportional to data. It is also possible to draw the chart with equal segment heights/widths, disregarding data points.

### Funnel Chart: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

## Menu commands

| Command              | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Properties...        | Opens the <b>Properties</b> dialog for the active sheet object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Notes                | Allows creating and sharing notes about the current object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Detach               | The chart title is appended with the text “(Detached)” and the chart is no longer updated with selections made in the document (though selections may actually still be made from the chart). The command is available only if the chart is attached. By making a copy of a chart and detaching it, you may make direct comparisons between the copy and the original.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Attach               | Attaches a detached chart. The chart becomes dynamically linked to the data. The command is available only if the chart is detached.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Set Reference        | This option sets a chart reference, such as a fixed plot of the chart with the current selections. When further selections are made in the document the reference plot remains, dimmed in the background. Chart axes will be adjusted to always include the maximum of the background data set and the current data set. The current data set is always plotted on top of the reference plot. Some portions of the reference plot may be obscured by the current data set plot. The display of reference chart plots is only possible in some chart types, such as bar charts, line charts, combo charts, radar charts, scatter charts, grid charts and gauge charts with needles. It is not possible to set a reference for a chart that contains a drill-down or a cyclic group. The reference will be lost when closing the document or when reloading data. The maximum number of objects that can be included when using the <b>Set Reference</b> option is 500. |
| Clear Reference      | This command is replaced with the <b>Set Reference</b> command when a reference is set. By choosing it the previously set reference will be cleared and the chart will revert to normal plot mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Clear All Selections | Clears all the current selections in the active sheet object. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Copy                 | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Print...             | Opens the selected sheet object(s) in tabular format in another browser window.<br><br>Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Send to Excel        | Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Export...            | Opens the <b>Save as</b> dialog where path, file name and (table) file type for the exported data content can be specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Command     | Details                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fast Change | Makes it possible to change the current chart into another chart type. Clicking on the  icon in the object caption (if shown) produces the same result. Only available if <b>Fast Type Change in Chart</b> has been enabled on the <b>Caption</b> tab of the <b>Properties</b> dialog.               |
| Minimize    | Iconizes the object. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if minimizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                   |
| Restore     | Restores a minimized or maximized object to its previous size and location. Double-clicking the icon of a minimized object or clicking the  icon in the object caption (if shown) of a maximized object produces the same result. This command is available only for minimized or maximized objects. |
| Maximize    | Enlarges the object to fill the sheet. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if maximizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                 |
| Remove      | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                                                                           |

## Funnel Chart Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

### Dimensions

This section describes the **Dimensions** property and its elements.

#### Dimension

Choose dimensions in the drop-down list. To add a dimension, click . Select a dimension in the drop-down. Use the  icon to move items in the list. The  icon removes items from the list. For more settings, click the **More...** button.

- **Enable Conditional:** Marking this check box hides or shows the dimension dynamically, depending on the value of a condition expression entered, by clicking the  button in the edit box below.
- **Dimension:** Displays the currently selected dimension.
- **Show Label:** Mark this check box to show a dimension label (the field name) on the x-axis.
- **Suppress Null Values:** If this check box is marked, the field selected as **Dimension** above will not be displayed in the chart if its value is NULL.
- **Show All Values:** Mark this check box to show all the dimension field values in the chart, including logically excluded values.
- **Show Axis Labels:** Mark this check box to show legend (names of field values) on the x-axis for the selected dimension field.

- **Limit Axis Label Characters:** Mark this check box to limit the length of the dimension value strings to be shown on axes and in the chart legend. Specify the number of characters in the input field, or drag the slider to the desired value. Truncated values will be followed by ... in the chart. This option can be used independently to the other options in this group.
- **Trellis Setting First Dimension:** Marking this check box will enable the trellis chart, where an array of charts that are based on the chart's first dimension are displayed.
- **Fixed Number of Columns:** Enter the number of columns you want the trellis chart to display. Specify the number of columns in the input field, or drag the slider to the desired value.
- **Fixed Number of Rows:** Enter the number of rows you want the trellis chart to display. Specify the number of rows in the input field, or drag the slider to the desired value.
- **Second Dimension:** Enables the second dimension in the trellis chart. If a secondary dimension is used, the first dimension values will be displayed as columns in the trellis matrix, whereas the secondary dimension values will be displayed as rows in the trellis matrix.

## Sort

Sets the sort order of the values in the sheet object. Some sort options may not be available for all sheet objects.

If more than one sort order is specified, the sort order will be state, expression, frequency, numeric, text, load order. **State** refers to the logical state (selected, optional, or excluded).

- **Primary Sort: Y-Value:** Sets whether the dimension values should be sorted according to the numeric value of the y-axis. This option is not available for calculated dimensions. **Frequency:** Sorts the field values by frequency (number of concurrences in the table). **Numeric Value:** Sorts the field values by their numeric values. **Text:** Sorts the field values in alphabetical order. **Load Order:** Sorts the field values by the initial load order.
- **Secondary Sort: Frequency:** Sorts the field values by frequency (number of concurrences in the table).  
**Numeric Value:** Sorts the field values by their numeric values.  
**Text:** Sorts the field values in alphabetical order.  
**Load Order:** Sorts the field values by the initial load order.
- **Sort by Expression:** Sorts the field values according to the expression entered.
- **Keep Selected on Top:** Enable this to keep the selected values on top.

## Limits

- **Restrict which values are displayed using the first expression:** These properties are used to determine how many dimension values are displayed in the chart, according to settings made below.
- **Show only:**
  - Select this option if you want to show the **First**, **Largest** or **Smallest** x number of values. If this option is set to 5, there will be five values displayed. If the dimension has **Show Others** enabled, the Others segment will take up one of the five display slots. The **First** option will return the rows based on the options selected on the **Sort** tab of the property dialog. If the chart is a Straight Table, the rows will be returned based on the primary sort at the time. In other words, a user can change the values display by double-clicking on any column header and making that column the primary sort. The **Largest** option returns the rows in descending

order based on the first expression in the chart. When used in a Straight Table, the dimension values shown will remain consistent while interactively sorting the expressions. The dimensions values will (may) change when the order of the expressions is changed. The **Smallest** option returns the rows in ascending order based on the first expression in the chart. When used in a Straight Table, the dimension values shown will remain consistent while interactively sorting the expressions. The dimensions values will (may) change when the order of the expressions is changed. Enter the number of values to display.

- The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- Select **Include Boundary Values** to include the dimension value that contains the comparison value.
- **Show only values that are:**
  - Select this option to display all dimensions values that meet the specified condition for this option.
  - Select to display values based on a percentage of the total, or on an exact amount.
  - The **relative to the total** option enables a relative mode which is similar to the **Relative** option on the **Expressions** tab of the property dialog.
  - The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Show only values that accumulate to:**
  - When this option is selected, all rows up to the current row are accumulated, and the result is compared to the value set in the option.
  - The **relative to the total** option enables a relative mode which is similar to the **Relative** option on the **Expressions** tab of the property dialog, and compares the accumulated values, based on first, largest or smallest values, to the overall total.
  - The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Show others:** Enabling this option will produce an **Others** segment in the chart. All dimension values that do not meet the comparison criteria for the display restrictions will be grouped into the **Others** segment. If there are dimensions after the selected dimension, **Collapse Inner Dimensions** will control whether individual values for the subsequent / inner dimensions display on the chart. In the **Label** field, enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text.
  - The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
  - If there are dimensions after the selected dimension, **Collapse Inner Dimensions** will control whether individual values for the subsequent / inner dimensions display on the chart.
- **Show Total:**
  - The chart will display a total for the selected dimension when this option is enabled. This total behaves differently than the expression total, which is still configured on the **Expressions** tab of the property dialog. **Label:** Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text.

- The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Use Global Grouping Mode:** The option only applies to inner dimensions. When this option is enabled the restrictions will be calculated on the selected dimension only. All previous dimensions will be ignored. If this is disabled, the restrictions are calculated based on all preceding dimensions.

## Expressions

Choose expressions in the drop-down list. To add an expression, click . Select an expression from the drop-down. Use the  icon to move items in the list. The  icon removes items from the list. For more information click the **More...** button.

## Expressions Tab

- **Enable:** Marking this check box will enable the selected expression. If the box is not marked, the expression will not be used at all.
- **Conditional:** Marking this check box hides or shows the expression dynamically, depending on the value of a condition expression entered, by clicking the *fx* button in the edit box below.
- **Label:**
  - The label of the expression. Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text.
  - The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Expression:** Displays the currently selected expression.
- **Comment:**
  - Enter a comment to describe the purpose and function of the expression.
  - The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Invisible:** Hides the expression.
- **Show in Percent (Relative):** The chart shows the result in percent instead of absolute numbers.
- **Value Display Settings:** Check this box to define how to display values. Click  to open the popup.
  - **Value Display Settings Popup:**
    - **Show Values on Datapoints:** Mark this check box to display the result of the expression as text on top of the data points.
    - **Text as Popup:** Mark this check box to have the result of the expression shown in the popup balloon messages appearing when hovering over a data point in a chart in the layout. This option can be used with or without any of the other display options. It is thus possible to have an expression that does not appear in the chart itself, but only in hover popups.

### Attribute Expression Styles

- **Background color:** Define an attribute expression for calculating the basic plot color of the data point. The expression used should return a valid color representation (a number representing the Red, Green and Blue components as defined in Visual Basic) which is typically achieved by using one of the special chart color functions. If the result of the expression is not a valid color representation, black will be used.
- **Number Format Tab:** Each field has a default number format which can be set in the Document Properties: Number page. It is however possible to use a separate number format for an individual sheet object. This property page applies to the active object and contains the following controls for formatting values:
  - **Number Format:** Choose a number format from the alternatives below.
  - **Default:** Both numbers and text. Numbers are shown in original format.
  - **Number:** Shows numeric values with the number of digits set in the **Precision** field.
  - **Integer:** Shows numeric values as integers.
  - **Fixed to:** Shows numeric values as decimal values with the number of decimal digits set in the **Decimals** field.
  - **Money:** Shows values in the format set in the **Format Pattern** field. The default format is the Windows Currency setting.
  - **Date:** Shows values that can be interpreted as dates in the format set in the **Format Pattern** field.
  - **Time:** Shows values that can be interpreted as time in the format set in the **Format Pattern** field.
  - **Timestamp:** Shows values that can be interpreted as date + time in the format set in the **Format Pattern** field.
  - **Interval:** Shows time as sequential time increments (e.g. format = mm shows the value as the number of minutes since calendar start (1899:12:30:24:00)).
  - **Format Pattern:** The format code that further specifies the display format of the field. **ISO** sets the format to the ISO standard. Only valid for **Date**, **Time**, **Timestamp** and **Interval**. **Sys** sets the format to the system settings.
  - **Precision:** The number of digits that will be displayed.
  - **Decimals:** Sets the number of decimals included.
  - **Decimals Separator:** Sets the symbol for decimal separators.
  - **Thousand Separator:** Sets the symbol for thousand separators.
  - **In Percent:** Shows formatting in percentage instead of absolute numbers. The setting is only available for **Number**, **Integer** and **Fixed to**.
  - **Preview:** Shows a preview of the number format specified above.

### Show Title

By default, the label of the first expression defined is set as chart title. Clear the check box if you do not wish to have a chart title. The title may be defined as a calculated formula for dynamic update. Click *fx* to open the **Edit Expression** dialog.

## More.../Less...

Click this button to expand/collapse the foldout that contains additional tabs. Depending on if the **Dimensions** or **Expressions** field is active, different tabs are displayed.

## Funnel Chart Properties: Presentation

This section describes **Presentation** properties.

### Color Style

Sets the color style of the chart.

### Orientation

Sets the orientation of the chart.

### Tip Width (%)

Defines the width of the funnel tip as a percentage of the funnel mouth width.

### Reverse Orientation

Enable this check box if you want to make the funnel point to the left or upwards.

### Show Legend

Displays the legend in the chart. Click  to open the popup.

### Legend Settings Popup

- **Legend Style:** Sets the legend style.
- **Vertical:** Sets the vertical alignment of the legend.
- **Line Spacing:** Specifies the distance between items in the legend.
- **Reverse Order:** To reverse the sort order of the legend mark this check box.
- **Wrap Cell Text:** If this check box is marked, the text of the legend items will be wrapped in two or more lines.

## Background

Sets the background of the chart.

The following sections describe the options are available.

### Color

The plot area will have a colored background. Click  to select a color.

### Image

The plot area will have an image background. Click  to change the image.

## Dynamic Image

Enter a calculated expression to show dynamic background images that change with the selection.

## Background Transparency

Enter a value in the box or drag the slider to set transparency for the chart.

## More.../Less...

This section settings the **More.../Less...** property.

## Popup Labels

By selecting this check box the values of the dimensions and expressions will appear as a pop-up balloon when hovering with the cursor over data point in the chart.

## Data Proportionality

This setting controls the degree to which the segments are proportional to the underlying data.

- **Equal Segment Heights:** No proportionality to data. Each segment is drawn with the same height (width for horizontal funnels) as all others. Typically only makes sense with numbers displayed in the chart.
- **Segment Height Proportional to Data:** Each segment is drawn with the a height (width for horizontal funnels) proportional to underlying data.
- **Segment Area Proportional to Data:** Each segment is drawn with the total area proportional to underlying data.

## Calculation Conditions

The expression entered here sets a condition to be fulfilled for the chart to be calculated. If the condition is not fulfilled, the text 'Calculation condition unfulfilled' will be displayed in the chart.

The value may be entered as a calculated formula.

Click *fx* to open the **Edit Expression** dialog.

## Styles

- **Legend:** To set the color of the legend click . To set the font color click . To set the font type click **Aa**.
- **Chart Title Style:** To set the font color of the chart title click . To set the font type click **Aa**.
- **Caption Font:** To set the caption font type click **Aa**.
- **Active Caption:** To set the background color for the active caption click . To set the text color click .

- **Inactive Caption:** To set the background color for the inactive caption click . To set the text color click .
- **Use Border:** Mark this check box in order to use a border around the sheet object. Click the  to set the color of the border.
- **Border Width:** Specify a value or drag the slider to set the width of the border. The width is specified in pixels.
- **Rounded Corners:** Click  to open the **Rounded Corners** popup.

***Rounded Corners** is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.*

- Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected.
- Select **Squareness** by entering a value.

## Text

- **Text in Chart:** Click  to add text in the chart.
- **Text:** The text added in **Text in Chart** are displayed here.
- **Tilt Angle:** Specify an angle between 0 and 360 degrees for the text. The default is 0.
- **Horizontal Align:** Sets the horizontal alignment.
- **On Top:** The text currently selected in the list will be forced to the foreground when drawing the chart.
- **Text Style:**
  - To set the background color for the text click .
  - To set the font color click . To set the font type click .
- **Text Position:** Sets the position and size of the text on the object.

## Funnel Chart Properties: Caption

This section describes **Caption** properties.

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.

The value may be entered as a calculated formula.

Click  to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.

- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

### More.../Less...

This section describes the **More.../Less...** property, which contains several options for **Icons in Caption**.

*Some options may not be available for all objects.*

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!
- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Maximize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.
- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.  
Click  to open the popup.

- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Funnel Chart Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.
- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.35 Mekko Chart - AJAX/Webview

Mekko charts present data using variable width bars. They can display up to three levels of data in a two-dimensional chart. Mekko charts are useful in such areas as market analysis.

### Mekko Chart: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

Menu commands

| Command              | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Properties...        | Opens the <b>Properties</b> dialog for the active sheet object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Notes                | Allows creating and sharing notes about the current object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Detach               | The chart title is appended with the text “(Detached)” and the chart is no longer updated with selections made in the document (though selections may actually still be made from the chart). The command is available only if the chart is attached. By making a copy of a chart and detaching it, you may make direct comparisons between the copy and the original.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Attach               | Attaches a detached chart. The chart becomes dynamically linked to the data. The command is available only if the chart is detached.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Set Reference        | This option sets a chart reference, such as a fixed plot of the chart with the current selections. When further selections are made in the document the reference plot remains, dimmed in the background. Chart axes will be adjusted to always include the maximum of the background data set and the current data set. The current data set is always plotted on top of the reference plot. Some portions of the reference plot may be obscured by the current data set plot. The display of reference chart plots is only possible in some chart types, such as bar charts, line charts, combo charts, radar charts, scatter charts, grid charts and gauge charts with needles. It is not possible to set a reference for a chart that contains a drill-down or a cyclic group. The reference will be lost when closing the document or when reloading data. The maximum number of objects that can be included when using the <b>Set Reference</b> option is 500. |
| Clear Reference      | This command is replaced with the <b>Set Reference</b> command when a reference is set. By choosing it the previously set reference will be cleared and the chart will revert to normal plot mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Clear All Selections | Clears all the current selections in the active sheet object. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Command       | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Copy          | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                                                                                                 |
| Print...      | Opens the selected sheet object(s) in tabular format in another browser window.<br><br>Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                           |
| Send to Excel | Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Clicking on the  icon in the object caption (if shown) produces the same result. |
| Export...     | Opens the <b>Save as</b> dialog where path, file name and (table) file type for the exported data content can be specified.                                                                                                                                                                                                                                                                                                                                        |
| Fast Change   | Makes it possible to change the current chart into another chart type. Clicking on the  icon in the object caption (if shown) produces the same result. Only available if <b>Fast Type Change in Chart</b> has been enabled on the <b>Caption</b> tab of the <b>Properties</b> dialog.                                                                                            |
| Minimize      | Iconizes the object. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if minimizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                                                                                              |
| Restore       | Restores a minimized or maximized object to its previous size and location. Double-clicking the icon of a minimized object or clicking the  icon in the object caption (if shown) of a maximized object produces the same result. This command is available only for minimized or maximized objects.                                                                           |
| Maximize      | Enlarges the object to fill the sheet. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if maximizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                                                                           |
| Remove        | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Mekko Chart Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

### Dimensions

Choose dimensions in the drop-down list. To add a dimension, click . Select a dimension in the drop-down. Use the  icon to move items in the list. The  icon removes items from the list. For more settings, click the **More...** button.

## Dimension

- **Enable Conditional:** Marking this check box hides or shows the dimension dynamically, depending on the value of a condition expression entered, by clicking the *fx* button in the edit box below.
- **Dimension:** Displays the currently selected dimension.
- **Show Label:** Mark this check box to show a dimension label (the field name) on the x-axis.
- **Suppress Null Values:** If this check box is marked, the field selected as **Dimension** above will not be displayed in the chart if its value is NULL.
- **Show All Values:** Mark this check box to show all the dimension field values in the chart, including logically excluded values.
- **Show Axis Labels:** Mark this check box to show legend (names of field values) on the x-axis for the selected dimension field.
- **Limit Axis Label Characters:** Mark this check box to limit the length of the dimension value strings to be shown on axes and in the chart legend. Specify the number of characters in the input field, or drag the slider to the desired value. Truncated values will be followed by ... in the chart. This option can be used independently to the other options in this group.
- **Trellis Setting First Dimension:** Marking this check box will enable the trellis chart, where an array of charts that are based on the chart's first dimension are displayed.
- **Fixed Number of Columns:** Enter the number of columns you want the trellis chart to display. Specify the number of columns in the input field, or drag the slider to the desired value.
- **Fixed Number of Rows:** Enter the number of rows you want the trellis chart to display. Specify the number of rows in the input field, or drag the slider to the desired value.
- **Second Dimension:** Enables the second dimension in the trellis chart. If a secondary dimension is used, the first dimension values will be displayed as columns in the trellis matrix, whereas the secondary dimension values will be displayed as rows in the trellis matrix.

## Sort

Sets the sort order of the values in the sheet object. Some sort options may not be available for all sheet objects.

If more than one sort order is specified, the sort order will be state, expression, frequency, numeric, text, load order. **State** refers to the logical state (selected, optional, or excluded).

- **Primary Sort: Y-Value:** Sets whether the dimension values should be sorted according to the numeric value of the y-axis. This option is not available for calculated dimensions. **Frequency:** Sorts the field values by frequency (number of concurrences in the table). **Numeric Value:** Sorts the field values by their numeric values. **Text:** Sorts the field values in alphabetical order. **Load Order:** Sorts the field values by the initial load order.
- **Secondary Sort: Frequency:** Sorts the field values by frequency (number of concurrences in the table).  
**Numeric Value:** Sorts the field values by their numeric values.  
**Text:** Sorts the field values in alphabetical order.  
**Load Order:** Sorts the field values by the initial load order.
- **Sort by Expression:** Sorts the field values according to the expression entered. The value may be

entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

- **Keep Selected on Top:** Enable this to keep the selected values on top.

### Limits

- **Restrict which values are displayed using the first expression:** These properties are used to determine how many dimension values are displayed in the chart, according to settings made below.
- **Show only:**  
Select this option if you want to show the **First**, **Largest** or **Smallest** x number of values. If this option is set to 5, there will be five values displayed. If the dimension has **Show Others** enabled, the Others segment will take up one of the five display slots.
  - The **First** option will return the rows based on the options selected on the **Sort** tab of the property dialog. If the chart is a Straight Table, the rows will be returned based on the primary sort at the time. In other words, a user can change the values display by double-clicking on any column header and making that column the primary sort.
  - The **Largest** option returns the rows in descending order based on the first expression in the chart. When used in a Straight Table, the dimension values shown will remain consistent while interactively sorting the expressions. The dimensions values will (may) change when the order of the expressions is changed.
  - The **Smallest** option returns the rows in ascending order based on the first expression in the chart. When used in a Straight Table, the dimension values shown will remain consistent while interactively sorting the expressions. The dimensions values will (may) change when the order of the expressions is changed.
  - Enter the number of values to display.

The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog. Select **Include Boundary Values** to include the dimension value that contains the comparison value.

- **Show only values that are:** Select this option to display all dimensions values that meet the specified condition for this option. Select to display values based on a percentage of the total, or on an exact amount. The **relative to the total** option enables a relative mode which is similar to the **Relative** option on the **Expressions** tab of the property dialog. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Show only values that accumulate to:** When this option is selected, all rows up to the current row are accumulated, and the result is compared to the value set in the option. The **relative to the total** option enables a relative mode which is similar to the **Relative** option on the **Expressions** tab of the property dialog, and compares the accumulated values (based on first, largest or smallest values) to the overall total. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Show Others:** Enabling this option will produce an **Others** segment in the chart. All dimension values that do not meet the comparison criteria for the display restrictions will be grouped into the **Others** segment. If there are dimensions after the selected dimension, **Collapse Inner Dimensions** will control whether individual values for the subsequent / inner dimensions display on the chart. In the **Label** field, enter the name you wish to display in the chart. If no text is entered, the label will be

automatically set to the expression text.

The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog. If there are dimensions after the selected dimension, **Collapse Inner Dimensions** will control whether individual values for the subsequent / inner dimensions display on the chart. If there are dimensions after the selected dimension, **Collapse Inner Dimensions** will control whether individual values for the subsequent / inner dimensions display on the chart.

- **Show Total:** The chart will display a total for the selected dimension when this option is enabled. This total behaves differently than the expression total, which is still configured on the **Expressions** tab of the property dialog. **Label:** Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Use Global Grouping Mode:** The option only applies to inner dimensions. When this option is enabled the restrictions will be calculated on the selected dimension only. All previous dimensions will be ignored. If this is disabled, the restrictions are calculated based on all preceding dimensions.

## Axis

- **Show Axis:** Check this box to show the axis.
- **Axis Width:** Enter the width of the axis and its tick marks, or drag the slider to the desired value.
- **Major Label:** Select **Horizontal**, **Vertical** or **Tilted** display of the major labels.
- **Minor Label:** Select **Horizontal**, **Vertical** or **Tilted** display of the minor labels.
- **Show Grid:** Check this box to show a grid in the chart originating from the tick marks of the x-axis. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Show Minor Grid:** Check this box to show minor lines in-between the grid lines. Only available if **Show Grid** is selected. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Stagger Labels:** Select this option to stagger x-axis labels when they become too many to show side by side.
- **Reverse Stagger:** X-axis labels are normally staggered bottom-up from left to right. When marking this check box, the stagger will be reversed to top-down.
- **Continuous X:** Sets the x-axis to be continuous, i.e. it will be interpreted numerically and shown with numerically correct intervals.
- **Force 0:** Fixes the lower edge of the chart to zero on the y-axis. This option is not available when a logarithmic axis is used.
- **Static Min:** Sets a fixed minimum value for the axis. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Max:** Sets a fixed maximum value for the axis. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Step:** Sets a fixed interval for tick marks on the axis. If this setting results in more than 100 tick marks, the value used will be modified. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

- **Backcast:** By entering an integer in the edit field, you force the x-axis to be extended to the left of the actual data points plotted. This is useful when using trend lines. The backcast line will be dotted. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Forecast:** By entering an integer in the edit field, you force the x-axis to be extended to the right of the actual data points plotted. This is useful when using trendlines. The forecast line will be dotted. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

## Expressions

Choose expressions in the drop-down list. To add an expression, click . Select an expression from the drop-down. Use the  icon to move items in the list. The  icon removes items from the list. For more information click the **More...** button.

### Expression

- **Enable:** Marking this check box will enable the selected expression. If the box is not marked, the expression will not be used at all.
- **Conditional:** Marking this check box hides or shows the expression dynamically, depending on the value of a condition expression entered, by clicking the *fx* button in the edit box below.
- **Label:** The label of the expression. Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Expression:** Displays the currently selected expression.
- **Comment:** Enter a comment to describe the purpose and function of the expression. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Invisible:** Hides the expression.
- **Show in Percent (Relative):** The chart shows the result in percent instead of absolute numbers.
- **Accumulate Expression:**

Check this box to accumulate expressions. Click  to open the popup.

- **Accumulation Popup:** Select one of the options to decide whether the values in the sheet object should be accumulated or not.
  - **Accumulate:** In an accumulated chart, each y-value is added to the y-value of the following x-value.
  - **No Accumulation:** The y-values of the selected chart expression will not be accumulated.
  - **Full Accumulation:** Each y-value accumulating all previous y-values of the expression. Full accumulation does not work if the chart trellis is enabled.
  - **Accumulation Steps:** Enter a number in the box or drag the slider to set the number of y-values in the expression to be accumulated.
- **Show in Legend:** When several expressions are used, this option displays a legend showing the expressions and their corresponding colors next to the chart.

- **Value Display Settings:**
  - **Show Values on Datapoints:** Mark this check box to display the result of the expression as text on top of the data points.
  - **Text as Popup:** Mark this check box to have the result of the expression shown in the popup balloon messages appearing when hovering over a data point in a chart in the layout. This option can be used with or without any of the other display options. It is thus possible to have an expression that does not appear in the chart itself, but only in hover popups.
  - **Text on Axis:** Plots the result of the expression at each x-axis value, the axis and the axis labels.
- **Attribute Expression Styles:**
  - **Background Color:** Define an attribute expression for calculating the basic plot color of the data point. The expression used should return a valid color representation (a number representing the Red, Green and Blue components as defined in Visual Basic) which is typically achieved by using one of the special chart color functions. If the result of the expression is not a valid color representation, black will be used.
  - **Number Format Tab:** Each field has a default number format which can be set in the Document Properties: Number page. It is however possible to use a separate number format for an individual sheet object. This property page applies to the active object and contains the following controls for formatting values:
    - **Number Format:** Choose a number format from the alternatives below.
    - **Default:** Both numbers and text. Numbers are shown in original format.
    - **Number:** Shows numeric values with the number of digits set in the **Precision** field.
    - **Integer:** Shows numeric values as integers.
    - **Fixed to:** Shows numeric values as decimal values with the number of decimal digits set in the **Decimals** field.
    - **Money:** Shows values in the format set in the **Format Pattern** field. The default format is the Windows Currency setting.
    - **Date:** Shows values that can be interpreted as dates in the format set in the **Format Pattern** field.
    - **Time:** Shows values that can be interpreted as time in the format set in the **Format Pattern** field.
    - **Timestamp:** Shows values that can be interpreted as date + time in the format set in the **Format Pattern** field.
    - **Interval:** Shows time as sequential time increments (e.g. format = mm shows the value as the number of minutes since calendar start (1899:12:30:24:00)).
    - **Format Pattern:** The format code that further specifies the display format of the field. **ISO** sets the format to the ISO standard. Only valid for **Date**, **Time**, **Timestamp** and **Interval**. **Sys** sets the format to the system settings.
    - **Precision:** The number of digits that will be displayed.
    - **Decimals:** Sets the number of decimals included.
    - **Decimals Separator:** Sets the symbol for decimal separators.

- **Thousand Separator:** Sets the symbol for thousand separators.
- **In Percent:** Shows formatting in percentage instead of absolute numbers. The setting is only available for **Number**, **Integer** and **Fixed to**.
- **Preview:** Shows a preview of the number format specified above.

### Axis

- **Show Axis:** Check this box to show the axis.
- **Axis Width:** Enter the width of the axis and its tick marks, or drag the slider to the desired value.
- **Split Axis:** Check this box to split the y-axis into two parts, thus creating an impression of two charts sharing a common x-axis.
- **Position:** Choose **Left** or **Right** position.
- **Show Grid:** Check this box to show a grid in the chart originating from the tick marks of the x-axis. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Show Minor Grid:** Check this box to show minor lines in-between the grid lines. Only available if **Show Grid** is selected. The grid lines can be formatted using the **Grid Style** and **Grid Color** settings.
- **Log Scale:** If this box is checked, the scale will be logarithmic.
- **Force 0:** Fixes the lower edge of the chart to zero on the y-axis. This option is not available when a logarithmic axis is used.
- **Static Min:** Sets a fixed minimum value for the axis. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Max:** Sets a fixed maximum value for the axis. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Step:** Sets a fixed interval for tick marks on the axis. If this setting results in more than 100 tick marks, the value used will be modified. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Static Center:** Sets a fixed value on the axis which will be positioned in the center of the plot area. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

### Show Title

By default, the label of the first expression defined is set as chart title. Clear the check box if you do not wish to have a chart title. The title may be defined as a calculated formula for dynamic update. Click *fx* to open the **Edit Expression** dialog.

### More.../Less...

Click this button to expand/collapse the foldout that contains additional tabs. Depending on if the **Dimensions** or **Expressions** field is active, different tabs are displayed.

## Mekko Chart Properties: Presentation

### Look

Select one of the available looks in the drop-down.

## Orientation

Sets the orientation of the chart.

## Color Style

Defines the color style on all plot colors in the chart. Click  to open the popup.

### Color Properties Popup

- **Persistent Colors:** Locks the colors assigned to each data point even if selections reduce the total number of data points. In this mode color representation will never change for a given data point, but there is a risk of having two adjacent bars or slices with the same color for different data points.
- **Repeat Last Color:** Select this check box to assign the last (18th) color to field values loaded as number 18 and forward. If this check box is left unselected, the 19th value (according to the original load order) will get the first color, the 20th value the second color, etc.

## Show Legend

Displays the legend in the chart. Click  to open the popup.

### Legend Settings Popup

- **Legend Style:** Sets the legend style.
- **Vertical:** Sets the vertical alignment of the legend.
- **Line Spacing:** Specifies the distance between items in the legend.
- **Reverse Order:** To reverse the sort order of the legend mark this check box.
- **Wrap Cell Text:** If this check box is marked, the text of the legend items will be wrapped in two or more lines.

## Background

Sets the background of the chart. The following options are available:

- **Color:** Click  to select a color.
- **Image:** Click  to change the image.
- **Dynamic Image:** Enter a calculated expression to show dynamic background images that change with the selection.

## Plot Area Background

Sets the background of the plot area. The following options are available:

- **Color:** The plot area will have a colored background. Click  to select a color.
- **Image:** The plot area will have an image background. Click  to change the image.

- **Dynamic Image:** Enter a calculated expression to show dynamic background images that change with the selection.

## Plot Area Style

This control can be used to change the appearance of the plot area background. The following options are available:

- **Frame:** A frame is drawn around the plot area.
- **Shadow:** This options gives a shadow effect on the plot area background.
- **Minimal:** The plot area background is removed.

## Background Transparency

Enter a value in the box or drag the slider to set transparency for the chart.

## More.../Les...

This section describes the elements in **More.../Less....**

### General

- **Reverse Direction:** When this check box is marked, the values shown in the chart will be reversed, i.e. if the 10 highest values are shown and the box is checked the chart will then show the 10 lowest values.
- **Max Values Shown:** In this box, specify an upper limit for how many data points to show values for in the chart. If no limit is specified, values will be shown for all data points, which may affect the readability of the chart.
- **Suppress Zero-Values:** If this check box is marked, all combinations of the dimension fields returning zero or null from all expressions will be disregarded in the calculation. This option is selected by default.
- **Suppress Missing:** If this check box is marked, all combinations of the dimension fields associated with only null values in all fields in all expressions will be disregarded in the calculation. This option is selected by default. Turning it off can be useful only in special cases, e.g. if null values is to be counted in a chart.
- **Synchronize Zero for Expression Axes:** Synchronizes the zero level of the two y-axes (left/right or top/bottom).
- **Vertical Numbers:** Shows the values vertically.
- **Plot Numbers on Segments:** Marking this check box will plot values on data points inside the segments instead of on top of them.
- **Popup Labels:** By selecting this check box the values of the dimensions and expressions will appear as a pop-up balloon when hovering with the cursor over data point in the chart.
- **Calculation Conditions:** The expression entered here sets a condition to be fulfilled for the chart to be calculated. If the condition is not fulfilled, the text 'Calculation condition unfulfilled' will be displayed in the chart. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.

## Styles

- **Legend:** To set the font type of the legend click .
- **Chart Title Style:** To set the font color of the chart title click . To set the font type click .
- **Caption Font:** To set the caption font type click .
- **Active Caption:** To set the background color for the active caption click . To set the text color click .
- **Inactive Caption:** To set the background color for the inactive caption click . To set the text color click .
- **Use Border:** Mark this check box in order to use a border around the sheet object. Click the  to set the color of the border.
- **Border Width:** Specify a value or drag the slider to set the width of the border. The width is specified in pixels.
- **Rounded Corners:** Click  to open the **Rounded Corners** popup.

***Rounded Corners** is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.*

- **Rounded Corners Popup:**
  - Select **Fixed** or **Relative** roundness of corners, and which corners to be affected.
  - Set a **Squareness** value by entering a value.
    - **Reference Lines:**
      - **Reference Lines:** Add a reference line by clicking .
      - **Show Label in Chart:** Displays the label next to the reference line.
      - **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
      - **X-Axis:** Select this option if the reference line should originate from the x-axis.
      - **Expression:** The value at which the reference line should be drawn. Enter an expression you wish to use as start point.
      - **Line Weight:** Specifies the weight of the reference line.
      - **Line Style:** Specifies the style of the reference line.
      - **Line Color:** Specifies the color of the reference line.

- **Use Show Condition:** The reference line will be shown or hidden depending on a conditional expression which will be evaluated each time the chart is to be drawn. The reference line will only be hidden when the expression returns FALSE.
- **Condition:** Enter the conditional expression. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Text:**
  - **Text in Chart:** Click  to add text in the chart.
  - **Text:** The text added in **Text in Chart** are displayed here.
  - **Tilt Angle:** Specify an angle between 0 and 360 degrees for the text. The default is 0.
  - **Horizontal Align:** Sets the horizontal alignment.
  - **On Top:** The text currently selected in the list will be forced to the foreground when drawing the chart.
  - **Text Style:**
    - To set the background color for the text click .
    - To set the font color click . To set the font type click .
  - **Size Position:** Sets the position and size of the text on the object.

## Mekko Chart Properties: Caption

This section describes **Caption** properties.

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.

The value may be entered as a calculated formula.

Click *fx* to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

### More.../Less...

This section describes the **More.../Less...** property and the elements inside its **Icons in Caption** element.

## Icons in Caption

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!
- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Maximize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.
- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.  
Click  to open the popup.
- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Mekko Chart Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.

- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.
- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click  , a row is added, highlight the row to unlock it and edit the user

information. To remove users click  after each user to be removed.

## 11.36 Block Chart - AJAX/WebView

The Block chart shows the relation between expression values as blocks of varying area. From a display standpoint it is related to the pie chart. The chart may be shown with either segment height/width or segment area proportional to data. It is also possible to draw the chart with equal segment heights/widths, disregarding data points.

## Block Chart: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

Menu commands

| Command              | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Properties...        | Opens the <b>Properties</b> dialog for the active sheet object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Notes                | Allows creating and sharing notes about the current object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Detach               | The chart title is appended with the text “(Detached)” and the chart is no longer updated with selections made in the document (though selections may actually still be made from the chart). The command is available only if the chart is attached. By making a copy of a chart and detaching it, you may make direct comparisons between the copy and the original.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Attach               | Attaches a detached chart. The chart becomes dynamically linked to the data. The command is available only if the chart is detached.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Set Reference        | This option sets a chart reference, such as a fixed plot of the chart with the current selections. When further selections are made in the document the reference plot remains, dimmed in the background. Chart axes will be adjusted to always include the maximum of the background data set and the current data set. The current data set is always plotted on top of the reference plot. Some portions of the reference plot may be obscured by the current data set plot. The display of reference chart plots is only possible in some chart types, such as bar charts, line charts, combo charts, radar charts, scatter charts, grid charts and gauge charts with needles. It is not possible to set a reference for a chart that contains a drill-down or a cyclic group. The reference will be lost when closing the document or when reloading data. The maximum number of objects that can be included when using the <b>Set Reference</b> option is 500. |
| Clear Reference      | This command is replaced with the <b>Set Reference</b> command when a reference is set. By choosing it the previously set reference will be cleared and the chart will revert to normal plot mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Clear All Selections | Clears all the current selections in the active sheet object. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Copy                 | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Print...             | Opens the selected sheet object(s) in tabular format in another browser window.<br><br>Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Command       | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Send to Excel | Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Clicking on the  icon in the object caption (if shown) produces the same result. |
| Export...     | Opens the <b>Save as</b> dialog where path, file name and (table) file type for the exported data content can be specified.                                                                                                                                                                                                                                                                                                                                        |
| Fast Change   | Makes it possible to change the current chart into another chart type. Clicking on the  icon in the object caption (if shown) produces the same result. Only available if <b>Fast Type Change in Chart</b> has been enabled on the <b>Caption</b> tab of the <b>Properties</b> dialog.                                                                                            |
| Minimize      | Iconizes the object. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if minimizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                                                                                                |
| Restore       | Restores a minimized or maximized object to its previous size and location. Double-clicking the icon of a minimized object or clicking the  icon in the object caption (if shown) of a maximized object produces the same result. This command is available only for minimized or maximized objects.                                                                             |
| Maximize      | Enlarges the object to fill the sheet. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if maximizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                                                                           |
| Remove        | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Block Chart Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

## Dimensions

Choose dimensions in the drop-down list. To add a dimension, click . Select a dimension in the drop-down. Use the  icon to move items in the list. The  icon removes items from the list. For more settings, click the **More...** button.

## Dimension

- **Enable Conditional:** Marking this check box hides or shows the dimension dynamically, depending on the value of a condition expression entered, by clicking the  button in the edit box below.
- **Dimension:** Displays the currently selected dimension.
- **Show Label:** Mark this check box to show a dimension label (the field name) on the x-axis.

- **Suppress Null Values:** If this check box is marked, the field selected as **Dimension** above will not be displayed in the chart if its value is NULL.
- **Show All Values:** Mark this check box to show all the dimension field values in the chart, including logically excluded values.
- **Show Axis Labels:** Mark this check box to show legend (names of field values) on the x-axis for the selected dimension field.
- **Trellis Setting First Dimension:** Marking this check box will enable the trellis chart, where an array of charts that are based on the chart's first dimension are displayed.
- **Fixed Number of Columns:** Enter the number of columns you want the trellis chart to display. Specify the number of columns in the input field, or drag the slider to the desired value.
- **Fixed Number of Rows:** Enter the number of rows you want the trellis chart to display. Specify the number of rows in the input field, or drag the slider to the desired value.
- **Second Dimension:** Enables the second dimension in the trellis chart. If a secondary dimension is used, the first dimension values will be displayed as columns in the trellis matrix, whereas the secondary dimension values will be displayed as rows in the trellis matrix.

### Limits

- **Restrict which values are displayed using the first expression:** These properties are used to determine how many dimension values are displayed in the chart, according to settings made below.
- **Show only:**  
Select this option if you want to show the **First**, **Largest** or **Smallest** x number of values. If this option is set to 5, there will be five values displayed. If the dimension has **Show Others** enabled, the Others segment will take up one of the five display slots.
  - The **First** option will return the rows based on the options selected on the **Sort** tab of the property dialog. If the chart is a Straight Table, the rows will be returned based on the primary sort at the time. In other words, a user can change the values display by double-clicking on any column header and making that column the primary sort.
  - The **Largest** option returns the rows in descending order based on the first expression in the chart. When used in a Straight Table, the dimension values shown will remain consistent while interactively sorting the expressions. The dimensions values will (may) change when the order of the expressions is changed.
  - The **Smallest** option returns the rows in ascending order based on the first expression in the chart. When used in a Straight Table, the dimension values shown will remain consistent while interactively sorting the expressions. The dimensions values will (may) change when the order of the expressions is changed.
  - Enter the number of values to display.  
The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog. Select **Include Boundary Values** to include the dimension value that contains the comparison value.
- **Show only values that are:** Select this option to display all dimensions values that meet the specified condition for this option. Select to display values based on a percentage of the total, or on an exact amount. The **relative to the total** option enables a relative mode which is similar to the

**Relative** option on the **Expressions** tab of the property dialog. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

- **Show only values that accumulate to:** When this option is selected, all rows up to the current row are accumulated, and the result is compared to the value set in the option. The **relative to the total** option enables a relative mode which is similar to the **Relative** option on the **Expressions** tab of the property dialog, and compares the accumulated values (based on first, largest or smallest values) to the overall total. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Show Others:** Enabling this option will produce an **Others** segment in the chart. All dimension values that do not meet the comparison criteria for the display restrictions will be grouped into the **Others** segment. If there are dimensions after the selected dimension, **Collapse Inner Dimensions** will control whether individual values for the subsequent / inner dimensions display on the chart. In the **Label** field, enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text.

The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog. If there are dimensions after the selected dimension, **Collapse Inner Dimensions** will control whether individual values for the subsequent / inner dimensions display on the chart.

- **Show Total:** The chart will display a total for the selected dimension when this option is enabled. This total behaves differently than the expression total, which is still configured on the **Expressions** tab of the property dialog. **Label:** Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Use Global Grouping Mode:** The option only applies to inner dimensions. When this option is enabled the restrictions will be calculated on the selected dimension only. All previous dimensions will be ignored. If this is disabled, the restrictions are calculated based on all preceding dimensions.

## Expressions

Choose expressions in the drop-down list. To add an expression, click . Select an expression from the drop-down. Use the  icon to move items in the list. The  icon removes items from the list. For more information click the **More...** button.

## Expression

- **Enable:** Marking this check box will enable the selected expression. If the box is not marked, the expression will not be used at all.
- **Conditional:** Marking this check box hides or shows the expression dynamically, depending on the value of a condition expression entered, by clicking the *fx* button in the edit box below.
- **Label:** The label of the expression. Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Expression:** Displays the currently selected expression.

- **Comment:** Enter a comment to describe the purpose and function of the expression. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Invisible:** Hides the expression.
- **Show in Percent (Relative):** The chart shows the result in percent instead of absolute numbers.
- **Show in Legend:** When several expressions are used, this option displays a legend showing the expressions and their corresponding colors next to the chart.
- **Value Display Settings: Show Values on Datapoints:** Mark this check box to display the result of the expression as text on top of the data points. **Text as Popup:** Mark this check box to have the result of the expression shown in the popup balloon messages appearing when hovering over a data point in a chart in the layout. This option can be used with or without any of the other display options. It is thus possible to have an expression that does not appear in the chart itself, but only in hover popups. **Text on Axis:** Plots the result of the expression at each x-axis value, the axis and the axis labels.
- **Attribute Expression Styles:**
  - **Background Color:** Define an attribute expression for calculating the basic plot color of the data point. The expression used should return a valid color representation (a number representing the Red, Green and Blue components as defined in Visual Basic) which is typically achieved by using one of the special chart color functions. If the result of the expression is not a valid color representation, black will be used.
  - **Text Color:** Define an attribute expression for calculating the text color of text associated with the data point. The expression used should return a valid color representation (a number representing the Red, Green and Blue components as defined in Visual Basic) which is typically achieved by using one of the special chart color functions. If the result of the expression is not a valid color representation, black will be used.
- **Number Format Tab:** Each field has a default number format which can be set in the Document Properties: Number page. It is however possible to use a separate number format for an individual sheet object. This property page applies to the active object and contains the following controls for formatting values:
  - **Number Format:** Choose a number format from the alternatives below.
  - **Default:** Both numbers and text. Numbers are shown in original format.
  - **Number:** Shows numeric values with the number of digits set in the **Precision** field.
  - **Integer:** Shows numeric values as integers.
  - **Fixed to:** Shows numeric values as decimal values with the number of decimal digits set in the **Decimals** field.
  - **Money:** Shows values in the format set in the **Format Pattern** field. The default format is the Windows Currency setting.
  - **Date:** Shows values that can be interpreted as dates in the format set in the **Format Pattern** field.
  - **Time:** Shows values that can be interpreted as time in the format set in the **Format Pattern** field.

- **Timestamp:** Shows values that can be interpreted as date + time in the format set in the **Format Pattern** field.
- **Interval:** Shows time as sequential time increments (e.g. format = mm shows the value as the number of minutes since calendar start (1899:12:30:24:00)).
- **Format Pattern:** The format code that further specifies the display format of the field. **ISO** sets the format to the ISO standard. Only valid for **Date**, **Time**, **Timestamp** and **Interval**. **Sys** sets the format to the system settings.
- **Precision:** The number of digits that will be displayed.
- **Decimals:** Sets the number of decimals included.
- **Decimals Separator:** Sets the symbol for decimal separators.
- **Thousand Separator:** Sets the symbol for thousand separators.
- **In Percent:** Shows formatting in percentage instead of absolute numbers. The setting is only available for **Number**, **Integer** and **Fixed to**.
- **Preview:** Shows a preview of the number format specified above.

## Show Title

By default, the label of the first expression defined is set as chart title. Clear the check box if you do not wish to have a chart title. The title may be defined as a calculated formula for dynamic update. Click  to open the **Edit Expression** dialog.

## More.../Less...

Click this button to expand/collapse the foldout that contains additional tabs. Depending on if the **Dimensions** or **Expressions** field is active, different tabs are displayed.

## Block Chart Properties: Presentation

### Look

Select one of the available looks in the drop-down.

### Color Style

Defines the color style on all plot colors in the chart. Click  to open the popup.

### Color Properties Popup

- **Persistent Colors:** Locks the colors assigned to each data point even if selections reduce the total number of data points. In this mode color representation will never change for a given data point, but there is a risk of having two adjacent bars or slices with the same color for different data points.
- **Repeat Last Color:** Select this check box to assign the last (18th) color to field values loaded as number 18 and forward. If this check box is left unselected, the 19th value (according to the original load order) will get the first color, the 20th value the second color, etc.

### Visible Levels

A block chart can display a maximum of three levels of blocks, equivalent to the three dimensions allowed. By selecting **1**, **2** or **3** you set the number of levels actually displayed.

## Intermediate Level Captions

Select this check box to have captions drawn on the intermediate dimension level in three-dimensional block charts.

## Show Dimension Labels

Check this alternative to include labels in the chart.

## Background

Sets the background of the plot area. Possible options are:

- **Color:** The plot area will have a colored background. Click  to select a color.
- **Image:** The plot area will have an image background. Click  to change the image.
- **Dynamic Image:** Enter a calculated expression to show dynamic background images that change with the selection.

## Background Transparency

Enter a value in the box or drag the slider to set transparency for the chart.

## More.../Less...

Click this button to expand/collapse the foldout that contains additional tabs.

## General

- **Popup Labels:** By selecting this check box the values of the dimension(s) and expression(s) will appear as a pop-up balloon when hovering with the cursor over data point in the chart.
- **1st Dimension Relative Total:** With this option, the percentage of the indicated 1st dimension value relative to the total is included in the pop-up.
- **2nd Dimension Relative Total:** The percentage of the indicated 2nd dimension value as defined within the indicated 1st dimension value relative to the total.
- **3rd Dimension Relative Total:** As above, but for the 3rd dimension level.
- **Value Relative First Dimension:** The percentage of the indicated block relative to the total of the indicated 1st dimension value.
- **Value Relative Second Dimension:** The percentage of the indicated block relative to the total of the indicated 2nd dimension value.
- **Calculation Conditions:** The expression entered here sets a condition to be fulfilled for the chart to be calculated. If the condition is not fulfilled, the text 'Calculation condition unfulfilled' will be displayed in the chart. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.

## Styles

- **Dimension Labels:** To set the font color click . To set the font type click .
- **Block Caption:** To set the background color for the block caption click . To set the font color click . To set the font type click .
- **Chart Title Style:** To set the font color click . To set the font type click .
- **Caption Font:** To set the caption font type click .
- **Active Caption:** To set the background color for the active caption click . To set the font color click .
- **Inactive Caption:** To set the background color for the inactive caption click . To set the font color click .
- **Use Border:** Mark this check box in order to use a border around the sheet object. Click the  to set the color of the border.
- **Border Width:** Specify the width of the border in the input field. The width is specified in pixels.
- **Rounded Corners:** Click  to open the **Rounded Corners** popup. **Rounded Corners** is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.
- **Rounded Corners Popup:** Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected. Also select **Squareness** by entering a value.

## Text

- **Text in Chart:** Click  to add text in the chart.
- **Text:** The text added in **Text in Chart** are displayed here.
- **Tilt Angle:** Specify an angle between 0 and 360 degrees for the text. The default is 0.
- **Horizontal Align:** Sets the horizontal alignment.
- **On Top:** The text currently selected in the list will be forced to the foreground when drawing the chart.
- **Text Style:** To set the background color for the text click . To set the font color click . To set the font type click .
- **Size Position:** Sets the position and size of the text on the object.

## Block Chart Properties: Caption

This section describes **Block Chart** properties.

## Caption

This section describes **Caption** settings.

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.  
The value may be entered as a calculated formula.

Click *fx* to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

## More.../Less...

### Icons in Caption

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!
- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Maximize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore,

this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.

- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.

It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.

- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.

Click  to open the popup.

- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Block Chart Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.
- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.

- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.37 Pivot Table - AJAX/Webview

The pivot table is one of the most powerful tools for analyzing data. It offers substantial functionality but is still easy to use. Pivot tables show dimensions and expressions in rows and columns, for example in cross tables. The data in pivot tables may be grouped. Pivot tables can show partial sums.

*After a reload, any expanded columns in a pivot table will be collapsed.*

### Pivot Table: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

Pivot Table: Object Menu commands

| Command       | Details                                                                                                                                                                                                                                                                                                                                                                |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Properties... | Opens the <b>Properties</b> dialog for the active sheet object.                                                                                                                                                                                                                                                                                                        |
| Notes         | Allows creating and sharing notes about the current object.                                                                                                                                                                                                                                                                                                            |
| Detach        | The chart title is appended with the text "(Detached)" and the chart is no longer updated with selections made in the document (though selections may actually still be made from the chart). The command is available only if the chart is attached. By making a copy of a chart and detaching it, you may make direct comparisons between the copy and the original. |
| Attach        | Attaches a detached chart. The chart becomes dynamically linked to the data. The command is available only if the chart is detached.                                                                                                                                                                                                                                   |
| Expand All    | Expands all expandable cells.                                                                                                                                                                                                                                                                                                                                          |
| Collapse All  | Collapses all collapsible cells.                                                                                                                                                                                                                                                                                                                                       |

| Command                      | Details                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Collapse Dimension Rows      | Collapses all dimension rows.                                                                                                                                                                                                                                                                                                                                                             |
| Collapse Dimension Columns   | Collapses all dimension columns.                                                                                                                                                                                                                                                                                                                                                          |
| Clear All Selections         | Clears all the current selections in the active sheet object. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                         |
| Copy                         | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                        |
| Copy cell value to clipboard | Copies the selected cell value to the clipboard.                                                                                                                                                                                                                                                                                                                                          |
| Minimize                     | Iconizes the object. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if minimizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                       |
| Restore                      | Restores a minimized or maximized object to its previous size and location. Double-clicking the icon of a minimized object or clicking the  icon in the object caption (if shown) of a maximized object produces the same result. This command is available only for minimized or maximized objects. |
| Maximize                     | Enlarges the object to fill the sheet. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if maximizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                  |
| Delete                       | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                                                                               |

## Pivot Table Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

### Dimensions

Choose dimensions in the drop-down list. To add a dimension, click . Select a dimension in the drop-down. Use the  icon to move items in the list. The  icon removes items from the list. For more settings, click the **More...** button.

### Dimension

- **Enable Conditional:** Marking this check box hides or shows the dimension dynamically, depending on the value of a condition expression entered, by clicking the  button in the edit box below.

- **Dimension:** Displays the currently selected dimension.
- **Label:** The label of the dimension. Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text. The value may be entered as a calculated formula. Click  $f_x$  to open the **Edit Expression** dialog.
- **Suppress Null Values:** If this check box is marked, the field selected as **Dimension** above will not be displayed in the chart if its value is NULL.
- **Show All Values:** Mark this check box to show all the dimension field values in the chart, including logically excluded values.
- **Dropdown Select:** If this check box is selected for a field column, a drop-down icon will appear to the left in the column header. By clicking the icon, a list box showing all field values of the field will be opened over the table. It is then possible to make selections and searches in the same manner as if the field had been a row in a multi box.
- **Show Partial Sums:** Displays partial sums in the sheet object.
- **Column Alignment:** Click  to open the popup.
  - **Column Alignment Popup:**
    - **Label:** Sets the alignment for the label to **Left** , **Centered** or **Right**.
    - **Data (Numeric):** Sets the alignment for the horizontal label to **Left** , **Centered** or **Right**.
    - **Data (Text):** Sets the alignment for text data to **Left** , **Centered** or **Right**.
- **Attribute Expression Styles:**
  - **Background Color:** Define an attribute expression for calculating the cell background color of the dimension cell. The expression used should return a valid color representation (a number representing the Red, Green and Blue components as defined in Visual Basic) which is typically achieved by using one of the special chart color functions. If the result of the expression is not a valid color representation, black will be used.
  - **Text Color:** Define an attribute expression for calculating the cell text color of the dimension cell. The expression used should return a valid color representation (a number representing the Red, Green and Blue components as defined in Visual Basic) which is typically achieved by using one of the special chart color functions. If the result of the expression is not a valid color representation, black will be used.
  - **Text Format:** Define an attribute expression for calculation of the font style of text in the table cell for each dimension cell. The expression used as text format expression should return a string containing a '<B>' for bold text, '<I>' for italic text and/or '<U>' for underlined text.

## Sort

Sets the sort order of the values in the sheet object. Some sort options may not be available for all sheet objects.

If more than one sort order is specified, the sort order will be state, expression, frequency, numeric, text, load order. **State** refers to the logical state (selected, optional, or excluded).

- **Primary Sort: Y-Value:** Sets whether the dimension values should be sorted according to the numeric value of the y-axis. This option is not available for calculated dimensions. **Frequency:** Sorts the field values by frequency (number of concurrences in the table). **Numeric Value:** Sorts the field

values by their numeric values. **Text**: Sorts the field values in alphabetical order. **Load Order**: Sorts the field values by the initial load order.

- **Secondary Sort: Frequency**: Sorts the field values by frequency (number of concurrences in the table).

**Numeric Value**: Sorts the field values by their numeric values.

**Text**: Sorts the field values in alphabetical order.

**Load Order**: Sorts the field values by the initial load order.

- **Sort by Expression**: Sorts the field values according to the expression entered. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Keep Selected on Top**: Enable this to keep the selected values on top.

## Expressions

Choose expressions in the drop-down list. To add an expression, click . Select an expression from the drop-down. Use the  icon to move items in the list. The  icon removes items from the list. For more information click the **More...** button.

## Expression

- **Enable**: Marking this check box will enable the selected expression. If the box is not marked, the expression will not be used at all.
- **Conditional**: Marking this check box hides or shows the expression dynamically, depending on the value of a condition expression entered, by clicking the *fx* button in the edit box below.
- **Label**: The label of the expression. Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Expression**: Displays the currently selected expression.
- **Comment**: Enter a comment to describe the purpose and function of the expression. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Representation**:

Choose a representation in the drop-down list. Depending on which representation is chosen different settings are shown.

- **Text**: No other settings
- **Image**: Click  to open the popup.
  - **Image Settings Popup**:
    - **Image Stretch: No Stretch**: Displays the image without stretching. This may cause parts of the picture to be invisible or only part of the object to be filled.
    - Fill**: The image is stretched to fit the object area without keeping the aspect ratio of the image.
    - Keep Aspect**: The image is stretched as far as possible to fill the object area while keeping the aspect ratio.
    - Fill with Aspect**: The image is stretched to fill the object area in both directions

while keeping the aspect ratio.

**Hide Text When Image is Missing:** No text will be displayed if QlikView cannot interpret the image reference.

- **Gauge:** Settings for the different Gauge alternatives:
  - **Gauge Min:** Specifies the minimum value of the gauge. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
  - **Gauge Max:** Specifies the maximum value of the gauge. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Mini Chart Field:** Choose the field for which the expression should be plotted. Click  to open the popup.
- **Mini Chart Mode Settings Popup:** Mini Chart Mode Settings Popup provides several settings for you to modify.
- **Mode:** Set the mini chart as sparklines, lines, dots, bars or whiskers.
- **Color:** Opens the Color dialog, where you can set the plot color of the mini chart.
- **Max Value Color:** Enable this setting and click  to open the Color dialog. You can set a color for the maximum value.
- **Min Value Color:** Enable this setting and click  to open the Color dialog. You can set a color for the minimum value.

*This setting is only available when Mode is set to Sparkline.*

- **Start Value Color:** Enable this setting and click  to open the Color dialog. You can set a color for the start values.

*This setting is not available for bars and whiskers.*

- **End Value Color:** Enable this setting and click  to open the Color dialog. You can set a color for the end values.

*This setting is not available for bars and whiskers.*

- **Force 0:** Fixes the lower edge of the chart to zero on the axis.

*Not available for whiskers.*

- **Shared Y-Axis Scale:** Forces all cells in the column to use the same y-axis scale.
  - **Link:** No other settings.
- **Column Alignment:** Click  to open the popup.
  - The popup contains the following items:
    - **Label:** Sets the alignment for the label to **Left**, **Centered** , or **Right**.
    - **Data (Numeric):** Sets the alignment for the horizontal label to **Left** , **Centered** or **Right**.
    - **Data (Text):** Sets the alignment for text data to **Left** , **Centered** , or **Right** .
- **Visual Cues:** Click  to open the popup.
  - **Visual Cues Popup:**
    - **Upper Limit:** Settings for the upper numeric interval value category. The numeric value above which the upper interval of numeric values begins is stated in the edit box. If this box is left empty no upper interval is defined.
    - **Normal:** Settings for the normal numeric interval value category. This interval is defined as all values between the upper limits and lower limits. By default, all numeric values fall within the normal interval.
    - **Lower Limit:** Settings for the lower numeric interval value category. The numeric value below which the lower interval of numeric values begins is stated in the edit box. If this box is left empty no lower interval is defined.
- **Attribute Expression Styles:**
  - **Background Color:** Define an attribute expression for calculating the cell background color of the dimension cell. The expression used should return a valid color representation (a number representing the Red, Green and Blue components as defined in Visual Basic) which is typically achieved by using one of the special chart color functions. If the result of the expression is not a valid color representation, black will be used.
  - **Text Color:** Define an attribute expression for calculating the cell text color of the dimension cell. The expression used should return a valid color representation (a number representing the Red, Green and Blue components as defined in Visual Basic) which is typically achieved by using one of the special chart color functions. If the result of the expression is not a valid color representation, black will be used.
  - **Text Format:** Define an attribute expression for calculation of the font style of text in the table cell for each dimension cell. The expression used as text format expression should return a string containing a '<B>' for bold text, '<I>' for italic text and/or '<U>' for underlined text.
    - **Number Format Tab:** Each field has a default number format which can be set in the Document Properties: Number page. It is however possible to use a separate number format for an individual sheet object. This property page applies to the active object and contains the following controls for formatting values:
      - **Number Format:** Choose a number format from the alternatives below.
      - **Default:** Both numbers and text. Numbers are shown in original format.

- **Number**: Shows numeric values with the number of digits set in the **Precision** field.
  - **Integer**: Shows numeric values as integers.
  - **Fixed to**: Shows numeric values as decimal values with the number of decimal digits set in the **Decimals** field.
  - **Money**: Shows values in the format set in the **Format Pattern** field. The default format is the Windows Currency setting.
  - **Date**: Shows values that can be interpreted as dates in the format set in the **Format Pattern** field.
  - **Time**: Shows values that can be interpreted as time in the format set in the **Format Pattern** field.
  - **Timestamp**: Shows values that can be interpreted as date + time in the format set in the **Format Pattern** field.
  - **Interval**: Shows time as sequential time increments (e.g. format = mm shows the value as the number of minutes since calendar start (1899:12:30:24:00)).
  - **Format Pattern**: The format code that further specifies the display format of the field. **ISO** sets the format to the ISO standard. Only valid for **Date**, **Time**, **Timestamp** and **Interval**. **Sys** sets the format to the system settings.
  - **Precision**: The number of digits that will be displayed.
  - **Decimals**: Sets the number of decimals included.
  - **Decimals Separator**: Sets the symbol for decimal separators.
  - **Thousand Separator**: Sets the symbol for thousand separators.
  - **In Percent**: Shows formatting in percentage instead of absolute numbers. The setting is only available for **Number**, **Integer** and **Fixed to**.
  - **Preview**: Shows a preview of the number format specified above.
- **More.../Less...**: Click this button to expand/collapse the foldout that contains additional tabs. Depending on if the **Dimensions** or **Expressions** field is active, different tabs are displayed.

## Pivot Table Properties: Presentation

This section describes **Pivot Table** properties.

### Indent Mode

If this check box is marked, the pivot table's left (column) dimensions will be displayed in indent mode. This means that the dimension values will replace the "Total" label, allowing for a compact display with just small indents between dimensions.

### Use Only First Dimension Label

This setting is only meaningful when a pivot table is in indent mode. By marking this check box the dimension label for the first dimension will occupy the entire label row. Dimension labels for subsequent dimensions will not be shown.

### Always Fully Expanded

If this check box is selected, all the dimensions are always fully expanded, and the expand/collapse functionality is turned off.

### Suppress Expansion Icons in Print

Select this check box if you do not want the '+' and '-' icons for partial expand and collapse to be visible when printing the pivot table.

### Selection Indicators

Displays selection indicators (beacons) in the table columns containing fields with selections.

### Populate Missing Cells

When this check box is marked, cells in cross tables representing missing combinations of dimensions will be mapped to a regular null value. Thereby it becomes possible to apply expressions testing for null and for attribute expressions and style formats to be applied.

### Total Position

Settings for display of totals in the pivot table.

### Allow Move Column and Pivoting

Deselect this check box to disable the drag-and-drop pivoting.

### Background Color

Sets the background to a color, either a solid color or a gradient. Click  to choose the color.

### Background Image

Sets an image as background. Click  to browse for an image. Click  to open the **Image** popup.

### Image Popup

**No Stretch:** Displays the image without stretching. This may cause parts of the picture to be invisible or only part of the object to be filled. **Fill:** The image is stretched to fit the object area without keeping the aspect ratio of the image. **Keep Aspect:** The image is stretched as far as possible to fill the object area while keeping the aspect ratio. **Fill with Aspect:** The image is stretched to fill the object area in both directions while keeping the aspect ratio. **Horizontal:** **Left**, **Centered** or **Right** alignment. **Vertical:** **Top**, **Centered** or **Bottom** alignment. **Transparency:** Set the level of transparency by entering a value or by dragging the slider. At 100% the background will be completely transparent.

### More.../Less...

This section describes the **More.../Less...** property, which contains the **General** property.

### General

This section describes the properties in **General**.

- **Style:** Choose an appropriate style from the drop-down list.
- **Cell Borders:** Click  to open the popup.
  - **Cell Border Settings Popup:**
    - **Vertical Dimension Cell Borders:** If this check box is deselected all vertical cell borders in dimension cells of the current style will be removed.
    - **Border Above Spacing:** If this check box is marked dimension spacing rows will be preceded by the same horizontal borders as those below. Furthermore all vertical borders will be removed within the spacing area.
    - **Vertical Expression Cell Borders:** If this check box is deselected all vertical cell borders in expression cells of the current style will be removed.
- **Suppress Zero-Values:** If this check box is marked, all combinations of the dimension fields returning zero or null from all expressions will be disregarded in the calculation. This option is selected by default.
- **Suppress Missing:** If this check box is marked, all combinations of the dimension fields associated with only null values in all fields in all expressions will be disregarded in the calculation. This option is selected by default. Turning it off can be useful only in special cases, e.g. if null values is to be counted in a chart.
- **Selection Indicators:** Displays selection indicators (beacons) in the table columns containing fields with selections.
- **Vertical Labels:** Displays the column titles vertically.
- **Null Symbol:** The symbol entered here will be used for displaying NULL values in the table.
- **Missing Symbol:** The symbol entered here will be used for displaying missing values in the table.
- **Wrap Header:** The contents of the header will be wrapped in two or more lines.
- **Wrap Cell Text:** The contents of the data cells will be wrapped in two or more lines.
- **Calculation Conditions:** The expression entered here sets a condition to be fulfilled for the chart to be calculated. If the condition is not fulfilled, the text 'Calculation condition unfulfilled' will be displayed in the chart. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.

## Styles

- **Font:** To set the font type click .
- **Caption Font:** To set the caption font type click .
- **Active Caption:** To set the background color for the active caption click . To set the text color click .
- **Inactive Caption:** To set the background color for the inactive caption click . To set the text color click .

- **Use Border:** Mark this check box in order to use a border around the sheet object. Click the  to set the color of the border.
- **Border Width:** Specify a value or drag the slider to set the width of the border. The width is specified in pixels.
- **Rounded Corners:** Click  to open the **Rounded Corners** popup.

*Rounded Corners is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.*

- **Rounded Corners Popup:**
  - Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected.
  - Select **Squareness** by entering a value.
- **Scrollbar Width:** Specify a value or drag the slider to set the width of the scroll bar. This control affects both the width and the relative size of the scroll bar symbols.

## Pivot Table Properties: Caption

This section describes **Pivot Table** properties.

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.  
The value may be entered as a calculated formula.

Click  to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

More.../Less...

**More.../Less...** has one property, **Icons in Caption**.

### Icon in Caption properties

This section describes properties in **Icons in Caption**.

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!
- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.
- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Maximize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.
- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.  
Click  to open the popup.
- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Pivot Table Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.

- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.
- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Normal:** Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized:** Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...:** The following options are available:
  - **Owner:** Domain and User Id of the owner.
  - **Share Object:** Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with:** Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID):** If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

## 11.38 Straight Table - AJAX/Webview

In opposition to the pivot table, the straight table cannot display subtotals or serve as a cross table. On the other hand, any of its columns can be sorted and each of its rows contains one combination of dimension (s)+expression(s).

### Straight Table: Object Menu

The object menu can be opened as a context menu by right-clicking on a sheet object, or by clicking the  icon in the object caption (if shown).

The commands in the menu may vary depending on whether WebView is used from inside QlikView or opening the document in a web browser. The menu contains the following commands:

## Object Menu properties

| Property                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Properties...                | Opens the <b>Properties</b> dialog for the active sheet object.                                                                                                                                                                                                                                                                                                                                                                                                      |
| Notes                        | Allows creating and sharing notes about the current object.                                                                                                                                                                                                                                                                                                                                                                                                          |
| Detach                       | The chart title is appended with the text “(Detached)” and the chart is no longer updated with selections made in the document (though selections may actually still be made from the chart). The command is available only if the chart is attached. By making a copy of a chart and detaching it, you may make direct comparisons between the copy and the original.                                                                                               |
| Attach                       | Attaches a detached chart. The chart becomes dynamically linked to the data. The command is available only if the chart is detached.                                                                                                                                                                                                                                                                                                                                 |
| Clear All Selections         | Clears all the current selections in the active sheet object. Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                                                    |
| Copy                         | Copies the selected sheet object(s) to the clipboard. This function only copies sheet objects, not data or images.                                                                                                                                                                                                                                                                                                                                                   |
| Copy cell value to clipboard | Copies the selected cell value to the clipboard.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Print...                     | Opens the selected sheet object(s) in tabular format in another browser window.<br><br>Clicking on the  icon in the object caption (if shown) produces the same result.                                                                                                                                                                                                           |
| Send to Excel                | Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Clicking on the  icon in the object caption (if shown) produces the same result. |
| Export...                    | Opens the <b>Save as</b> dialog where path, file name and (table) file type for the exported data content can be specified.                                                                                                                                                                                                                                                                                                                                          |
| Fast Change                  | Makes it possible to change the current chart into another chart type. Clicking on the  icon in the object caption (if shown) produces the same result. Only available if <b>Fast Type Change in Chart</b> has been enabled on the <b>Caption</b> tab of the <b>Properties</b> dialog.                                                                                            |
| Minimize                     | Iconizes the object. Clicking on the  icon in the object caption (if shown) produces the same result. This command is available only if minimizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                                                                                                |

| Property | Description                                                                                                                                                                                                                                                                                                                                                                             |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Restore  | Restores a minimized or maximized object to its previous size and location. Double-clicking the icon of a minimized object or clicking the  icon in the object caption (if shown) of a maximized object produces the same result. This command is available only for minimized or maximized objects. |
| Maximize | Enlarges the object to fill the sheet. Clicking on the <input type="checkbox"/> icon in the object caption (if shown) produces the same result. This command is available only if maximizing is allowed in the object's <b>Properties</b> dialog on the <b>Caption</b> page.                                                                                                            |
| Remove   | Removes the selected object from the sheet.                                                                                                                                                                                                                                                                                                                                             |

## Straight Table Properties

The **Properties** dialog is opened by selecting **Properties** from the **Object** menu. If the **Properties** command is dimmed, you probably do not have the privileges necessary to perform property changes.

### Dimensions

Choose dimensions in the drop-down list. To add a dimension, click . Select a dimension in the drop-down. Use the  icon to move items in the list. The  icon removes items from the list. For more information click the **More...** button.

### Dimension

- **Enable Conditional:** Marking this check box hides or shows the dimension dynamically, depending on the value of a condition expression entered, by clicking the *fx* button in the edit box below.
- **Dimension:** Displays the currently selected dimension.
- **Label:** The label of the dimension. Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text.
  - The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Suppress Null Values:** If this check box is marked, the field selected in the **Used Dimensions** above will not be displayed in the chart if its value is NULL.
- **Show All Values:** Select this box to show all the dimension field values in the chart, including logically excluded values.
- **Dropdown Select:** If this check box is selected for a field column, a drop-down icon will appear to the left in the column header. By clicking the icon, a list box showing all field values of the field will be opened over the table. It is then possible to make selections and searches in the same manner as if the field had been a row in a multi box.
- **Show Column:** When the check box is enabled, the column will be visible.
- **Conditional:** Enable the check box to show or hide the column depending on a condition expression which will be evaluated each time the table is drawn. The column will only be hidden when the

condition returns FALSE. Enter the conditional expression in the box below. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

- **Column Alignment:** Click  to open the popup.
  - **Column Alignment Popup:**
    - **Label:** Sets the alignment for the label to **Left**, **Centered**, or **Right**.
    - **Data (Numeric):** Sets the alignment for the horizontal label to **Left**, **Centered**, or **Right**.
    - **Data (Text):** Sets the alignment for text data to **Left**, **Centered**, or **Right**.
- **Attribute Expression Styles:**
  - **Background Color:** Define an attribute expression for calculating the cell background color of the dimension cell. The expression used should return a valid color representation (a number representing the Red, Green and Blue components as defined in Visual Basic) which is typically achieved by using one of the special chart color functions. If the result of the expression is not a valid color representation, black will be used.
  - **Text Color:** Define an attribute expression for calculating the cell text color of the dimension cell. The expression used should return a valid color representation (a number representing the Red, Green and Blue components as defined in Visual Basic) which is typically achieved by using one of the special chart color functions. If the result of the expression is not a valid color representation, black will be used.
  - **Text Format:** Define an attribute expression for calculation of the font style of text in the table cell for each dimension cell. The expression used as text format expression should return a string containing a '<B>' for bold text, '<I>' for italic text and/or '<U>' for underlined text.

## Sort

Here the sort order of the values in the sheet object, is set. Some sort options may not be available for some sheet objects.

If more than one sort order is specified, the sort order will be state, expression, frequency, numeric, text, load order.

- **Primary Sort:**
  - **Y-Value:** Sets whether the dimension values should be sorted according to the numeric value of the y-axis. This option is not available for calculated dimensions.
  - **Frequency:** Sorts the field values by frequency (number of concurrences in the table).
  - **Numeric Value:** Sorts the field values by their numeric values.
  - **Text:** Sorts the field values in alphabetical order.
  - **Load Order:** Sorts the field values by the initial load order.
- **Secondary Sort: Frequency:** Sorts the field values by frequency (number of concurrences in the table).
  - Numeric Value:** Sorts the field values by their numeric values.
  - Text:** Sorts the field values in alphabetical order.
  - Load Order:** Sorts the field values by the initial load order.

- **Sort by Expression:** Sorts the field values according to the expression entered.
  - The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Keep Selected on Top:** Enable this to keep the selected on top.

## Limits

Restrict which values are displayed using the first expression

These properties are used to determine how many dimension values are displayed in the chart, according to settings made below.

- **Show only:**

Select this option if you want to show the **First**, **Largest** or **Smallest** x number of values. If this option is set to 5, there will be five values displayed. If the dimension has **Show Others** enabled, the Others segment will take up one of the five display slots.

  - The **First** option will return the rows based on the options selected on the **Sort** tab of the property dialog. If the chart is a Straight Table, the rows will be returned based on the primary sort at the time. In other words, a user can change the values display by double-clicking on any column header and making that column the primary sort.
  - The **Largest** option returns the rows in descending order based on the first expression in the chart. When used in a Straight Table, the dimension values shown will remain consistent while interactively sorting the expressions. The dimensions values will (may) change when the order of the expressions is changed.
  - The **Smallest** option returns the rows in ascending order based on the first expression in the chart. When used in a Straight Table, the dimension values shown will remain consistent while interactively sorting the expressions. The dimensions values will (may) change when the order of the expressions is changed.
  - Enter the number of values to display.
- The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- Select **Include Boundary Values** to include the dimension value that contains the comparison value.
- **Show only values that are:**
  - Select this option to display all dimensions values that meet the specified condition for this option.
  - Select to display values based on a percentage of the total, or on an exact amount.
  - The **relative to the total** option enables a relative mode which is similar to the **Relative** option on the **Expressions** tab of the property dialog.
    - The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Show only values that accumulate to:**
  - When this option is selected, all rows up to the current row are accumulated, and the result is compared to the value set in the option.

- The **relative to the total** option enables a relative mode which is similar to the **Relative** option on the **Expressions** tab of the property dialog, and compares the accumulated values (based on first, largest or smallest values) to the overall total.
- The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Show Others:**
  - Enabling this option will produce an **Others** segment in the chart. All dimension values that do not meet the comparison criteria for the display restrictions will be grouped into the **Others** segment. If there are dimensions after the selected dimension, **Collapse Inner Dimensions** will control whether individual values for the subsequent / inner dimensions display on the chart. In the **Label** field, enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text.
  - The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
  - If there are dimensions after the selected dimension, **Collapse Inner Dimensions** will control whether individual values for the subsequent / inner dimensions display on the chart.
- **Show Total:**
  - The chart will display a total for the selected dimension when this option is enabled. This total behaves differently than the expression total, which is still configured on the **Expressions** tab of the property dialog. **Label:** Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text.
  - The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.
- **Use Global Grouping Mode:** The option only applies to inner dimensions. When this option is enabled the restrictions will be calculated on the selected dimension only. All previous dimensions will be ignored. If this is disabled, the restrictions are calculated based on all preceding dimensions.

## Expressions

Choose expressions in the drop-down list. To add a dimension, click . Select an expression the drop-down. Use the  icon to move items in the list. The  icon removes items from the list. For more information click the **More...** button.

### Expression

- **Enable:** Marking this check box will enable the selected expression. If the box is not marked, the expression will not be used at all.
- **Conditional:** Marking this check box hides or shows the expression dynamically, depending on the value of a condition expression entered, by clicking the *fx* button in the edit box below.
- **Label:** The label of the expression. Enter the name you wish to display in the chart. If no text is entered, the label will be automatically set to the expression text.
- **Expression:** The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog. Displays the currently selected expression.

- **Comment:** Enter a comment to describe the purpose and function of the expression. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
- **Show Column:** When the check box is selected, the column is visible.
- **Conditional:** Enable the check box to show or hide the column depending on a condition expression which will be evaluated each time the table is drawn. The column will only be hidden when the condition returns FALSE. Enter the conditional expression in the box below. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
- **Invisible:** Hides the expression.
- **Show in Percent (Relative):** The chart shows the result in percent instead of absolute numbers.
- **Representation:**

Choose a representation in the drop-down list. Depending on which representation is chosen different settings are shown.

  - **Text:** No other settings
  - **Image:** Click  to open the popup.
    - **Image Settings Popup:**
      - **Image Stretch:No Stretch:** Displays the image without stretching. This may cause parts of the picture to be invisible or only part of the object to be filled.
      - Fill:** The image is stretched to fit the object area without keeping the aspect ratio of the image.
      - Keep Aspect:** The image is stretched as far as possible to fill the object area while keeping the aspect ratio.
      - Fill with Aspect:** The image is stretched to fill the object area in both directions while keeping the aspect ratio.
      - Hide Text When Image is Missing:** No text will be displayed if QlikView cannot interpret the image reference.
    - **Gauge:** Settings for the different Gauge alternatives:
      - **Gauge Min:** Specifies the minimum value of the gauge. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
      - **Gauge Max:** Specifies the maximum value of the gauge. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.
    - **Mini Chart Field:** Choose the field for which the expression should be plotted.

Click  to open the popup.
    - **Mini Chart Mode Settings Popup:** Mini Chart Mode Settings Popup provides several settings for you to modify.
    - **Mode:** Set the mini chart as sparklines, lines, dots, bars or whiskers.
    - **Color:** Opens the Color dialog, where you can set the plot color of the mini chart.

- **Max Value Color:** Enable this setting and click  to open the Color dialog. You can set a color for the maximum value.
- **Min Value Color:** Enable this setting and click  to open the Color dialog. You can set a color for the minimum value.

*This setting is only available when Mode is set to Sparkline.*

- **Start Value Color:** Enable this setting and click  to open the Color dialog. You can set a color for the start values.

*This setting is not available for bars and whiskers.*

- **End Value Color:** Enable this setting and click  to open the Color dialog. You can set a color for the end values.

*This setting is not available for bars and whiskers.*

- **Force 0:** Fixes the lower edge of the chart to zero on the axis.

*Not available for whiskers.*

- **Shared Y-Axis Scale:** Forces all cells in the column to use the same y-axis scale.
- **Link:** No other settings.
- **Column Alignment:** Click  to open the popup.
  - Column Alignment Popup: **Label** sets the alignment for the label to **Left**, **Centered**, or **Right**.
  - Data (Numeric): Sets the alignment for the horizontal label to **Left**, **Centered**, or **Right**.
  - Data (Text): Sets the alignment for text data to **Left**, **Centered**, or **Right**.
- **Visual Cues:** Click  to open the popup.
  - Visual Cues Popup:
    - Upper Limit: Settings for the upper numeric interval value category. The numeric value above which the upper interval of numeric values begins is stated in the edit box. If this box is left empty no upper interval is defined.
    - Normal: Settings for the normal numeric interval value category. This interval is defined as all values between the upper limits and lower limits. By default, all numeric values fall within the normal interval.
    - Lower Limit: Settings for the lower numeric interval value category. The numeric value below which the lower interval of numeric values begins is stated in the edit box. If this box is left empty no lower interval is defined.

- **Use Expression Total:**

Check this box to use expression total. Click  to open the popup.

Total Popup

**Total Mode**

Select one of the options in the drop-down list to decide how the total of the selected expression is to be calculated.

**No Totals**

No total will be calculated for the expression.

**Expression Totals**

The expression total will be calculated using all the values of the field. If, e.g., the selected column contains the average salaries for different business categories, choosing the **Expression Totals** option will result in the average salary for all the business categories.

**Aggregation of Rows**

The individual values of each data point (each bar in a bar chart, each row in a straight table etc.) for the selected expression will be summed up, aggregated, using the selected aggregation function (typically summed up). Choose an aggregation function in the edit box.

- **Accumulate Expression:**

Check this box to accumulate expressions. Click  to open the popup.

- **Accumulation Popup:** Select one of the options to decide whether the values in the sheet object should be accumulated or not.

- **Accumulate:** In an accumulated chart, each y-value is added to the y-value of the following x-value.
- **No Accumulation:** The y-values of the selected chart expression will not be accumulated.
- **Full Accumulation:** Each y-value accumulating all previous y-values of the expression. Full accumulation does not work if the chart trellis is enabled.
- **Accumulation Steps:** Enter a number in the box or drag the slider to set the number of y-values in the expression to be accumulated.

- **Attribute Expression Styles:**

- **Background Color:** Define an attribute expression for calculating the cell background color of the dimension cell. The expression used should return a valid color representation (a number representing the Red, Green and Blue components as defined in Visual Basic) which is typically achieved by using one of the special chart color functions. If the result of the expression is not a valid color representation, black will be used.
- **Text Color:** Define an attribute expression for calculating the cell text color of the dimension cell. The expression used should return a valid color representation (a number representing the Red, Green and Blue components as defined in Visual Basic) which is typically achieved by using one of the special chart color functions. If the result of the expression is not a valid color representation, black will be used.

- **Text Format:** Define an attribute expression for calculation of the font style of text in the table cell for each dimension cell. The expression used as text format expression should return a string containing a '<B>' for bold text, '<I>' for italic text and/or '<U>' for underlined text.

## Sort

Sets the sort order of the values in the sheet object. Some sort options may not be available for all sheet objects.

If more than one sort order is specified, the sort order will be state, expression, frequency, numeric, text, load order. **State** refers to the logical state (selected, optional, or excluded).

- **Primary Sort:**
  - **Y-Value:** Sets whether the dimension values should be sorted according to the numeric value of the y-axis. This option is not available for calculated dimensions.
  - **Frequency:** Sorts the field values by frequency (number of concurrences in the table).
  - **Numeric Value:** Sorts the field values by their numeric values.
  - **Text:** Sorts the field values in alphabetical order.
  - **Load Order:** Sorts the field values by the initial load order.
- **Secondary Sort:**
  - **Frequency:** Sorts the field values by frequency (number of concurrences in the table).
  - **Numeric Value:** Sorts the field values by their numeric values.
  - **Text:** Sorts the field values in alphabetical order.
  - **Load Order:** Sorts the field values by the initial load order.
- **Sort by Expression:**

### Sort by Expression

Sorts the field values according to the expression entered.

The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

**Keep Selected on Top:** Enable this to keep the selected on top.

- **Number Format Tab:** Each field has a default number format which can be set in the Document Properties: Number page. It is however possible to use a separate number format for an individual sheet object. This property page applies to the active object and contains the following controls for formatting values:
  - **Number Format:** Choose a number format from the alternatives below.
  - **Default:** Both numbers and text. Numbers are shown in original format.
  - **Number:** Shows numeric values with the number of digits set in the **Precision** field.
  - **Integer:** Shows numeric values as integers.
  - **Fixed to:** Shows numeric values as decimal values with the number of decimal digits set in the **Decimals** field.
  - **Money:** Shows values in the format set in the **Format Pattern** field. The default format is the Windows Currency setting.
  - **Date:** Shows values that can be interpreted as dates in the format set in the **Format Pattern** field.

- **Time:** Shows values that can be interpreted as time in the format set in the **Format Pattern** field.
- **Timestamp:** Shows values that can be interpreted as date + time in the format set in the **Format Pattern** field.
- **Interval:** Shows time as sequential time increments (e.g. format = mm shows the value as the number of minutes since calendar start (1899:12:30:24:00)).
- **Format Pattern:** The format code that further specifies the display format of the field. **ISO** sets the format to the ISO standard. Only valid for **Date**, **Time**, **Timestamp** and **Interval**. **Sys** sets the format to the system settings.
- **Precision:** The number of digits that will be displayed.
- **Decimals:** Sets the number of decimals included.
- **Decimals Separator:** Sets the symbol for decimal separators.
- **Thousand Separator:** Sets the symbol for thousand separators.
- **In Percent:** Shows formatting in percentage instead of absolute numbers. The setting is only available for **Number**, **Integer** and **Fixed to**.
- **Preview:** Shows a preview of the number format specified above.

### More.../Less...

Click this button to expand/collapse the foldout that contains additional tabs. Depending on if the **Dimensions** or **Expressions** field is active, different tabs are displayed.

## Straight Table Properties: Presentation

This section describes **Straight Table** properties.

### Allow Interactive Sort

Deselecting this check box will disable the **Sort** command of the object menu.

### Max Number

Enter a number or drag the slider to set the maximum number of rows to display. Rows displaying sums are not counted; however, sums will still be calculated using all the rows of the table.

### Suppress Header Row

If this check box is marked the table will be shown without header (label) row.

### Sort Indicators

If this check box is selected, a sort indicator icon (arrow) will be shown in the header of the column, which is at the top of the current column sort order. The direction of the icon indicates whether the column is sorted ascending or descending.

### Selection Indicators

Displays selection indicators (beacons) in the table columns containing fields with selections.

### Total Position

Settings for display of totals in the straight table.

## Allow Move Column

Deselect this check box to disable moving columns.

## Background Color

Sets the background to a color, either a solid color or a gradient. Click  to choose the color.

## Background Image

Sets an image as background. Click  to browse for an image. Click  to open the **Image** popup.

## Image Popup

- **No Stretch:** Displays the image without stretching. This may cause parts of the picture to be invisible or only part of the object to be filled.
- **Fill:** The image is stretched to fit the object area without keeping the aspect ratio of the image.
- **Keep Aspect:** The image is stretched as far as possible to fill the object area while keeping the aspect ratio.
- **Fill with Aspect:** The image is stretched to fill the object area in both directions while keeping the aspect ratio.
- **Horizontal:** **Left**, **Centered** or **Right** alignment.
- **Vertical:** **Top**, **Centered** or **Bottom** alignment.
- **Transparency:** Set the level of transparency by entering a value or by dragging the slider. At 100% the background will be completely transparent.

## More.../Less...

Click this button to expand/collapse the foldout that contains additional tabs.

## General

- **Style:** Choose an appropriate style from the drop-down list.
- **Stripes Every:** Specify if and how long intervals in rows, shaded stripes should appear.
- **Cell Borders:** Click  to open the popup.
  - **Cell Border Settings Popup:**
    - **Vertical Dimension Cell Borders:** If this check box is deselected all vertical cell borders in dimension cells of the current style will be removed.
    - **Vertical Expression Cell Borders:** If this check box is deselected all vertical cell borders in expression cells of the current style will be removed.
    - **Border Above Spacing:** If this check box is marked dimension spacing rows will be preceded by the same horizontal borders as those below. Furthermore all vertical borders will be removed within the spacing area.

- **Suppress Zero-Values:** If this check box is marked, all combinations of the dimension fields returning zero or null from all expressions will be disregarded in the calculation. This option is selected by default.
- **Suppress Missing:** If this check box is marked, all combinations of the dimension fields associated with only null values in all fields in all expressions will be disregarded in the calculation. This option is selected by default. Turning it off can be useful only in special cases, e.g. if null values is to be counted in a chart.
- **Horizontal Label:** Mark this checkbox to display the straight table transposed 90 degrees, so that labels from a left column and each table record becomes a column of data. Some clients may not handle this setting!
- **Vertical Labels:** Displays the column titles vertically.
- **Null Symbol:** The symbol entered here will be used for displaying NULL values in the table.
- **Missing Symbol:** The symbol entered here will be used for displaying missing values in the table.
- **Wrap Header:** The contents of the header will be wrapped in two or more lines.
- **Wrap Cell Text:** If this check box is marked, the contents of the data cells will be wrapped in two or more lines.
- **Calculation Conditions:** The expression entered here sets a condition to be fulfilled for the chart to be calculated. If the condition is not fulfilled, the text 'Calculation condition unfulfilled' will be displayed in the chart. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.

## Styles

- **Font:** To set the font type click .
- **Caption Font:** To set the caption font type click .
- **Active Caption:** To set the background color for the active caption click . To set the text color click .
- **Inactive Caption:** To set the background color for the inactive caption click . To set the text color click .
- **Use Border:** Mark this check box in order to use a border around the sheet object. Click the  to set the color of the border.
- **Border Width:** Specify a value or drag the slider to set the width of the border. The width is specified in pixels.
- **Rounded Corners:** Click  to open the **Rounded Corners** popup.

*Rounded Corners is only available if you have selected **Advanced Styling Mode** in **Document Properties: General**.*

- **Rounded Corners Popup:** Select **Fixed** or **Relative** roundness of the corners, and which corners to be affected. Also select **Squareness** by entering a value.
- **Scroll Bar Width:** Specify a value or drag the slider to set the width of the scroll bar. This control affects both the width and the relative size of the scroll bar symbols.

## Straight Table Properties: Caption

This section describes **Straight Table** properties.

- **Label:** In the text box you can enter a title to be shown in the caption of the sheet object. If no **Label** is set, the name of the field will be used if **Show Caption** is selected.

The value may be entered as a calculated formula.

Click *fx* to open the **Edit Expression** dialog.

- **Show Caption:** When this option has been checked a caption will be drawn at the top of the sheet object. List boxes and other "box objects" will have the option switched on by default whereas buttons, text objects and line/arrow objects will not.
- **Caption Alignment:** Can be Left, Centered, or Right.
- **Multi Line Caption (Word Wrap):** If this option is checked, the text will be displayed in two or more rows.
- **Number of Rows:** If multiple lines are allowed for the caption, specify the number of rows in the input field, or drag the slider to the desired number.
- **Caption Alignment:** Can be Top, Centered, or Bottom.

## More.../Less...

This section describes **More.../Less...** properties.

### Icons in caption

- **Menu:** Opens the object menu.
- **Clear:** Clears all the current selections in the active sheet object.
- **Print:** Opens the selected sheet object(s) in tabular format in another browser window. Some clients may not handle this setting!
- **Copy Data:** Copies the field values in the sheet object. Some clients may not handle this setting!
- **Copy Image to Clipboard:** Copies the sheet object as an image to the Clipboard. Some clients may not handle this setting!
- **Send to Excel:** Exports possible (including selected) values to Microsoft Excel, which is automatically launched if not already running. The exported values will appear as one column in a new Excel worksheet. For this functionality to work Microsoft Excel 2007 or later must be installed on the computer. Some clients may not handle this setting!
- **Allow Minimize:** When this option has been checked a minimize icon will be displayed in the window caption of the sheet object, providing that it is possible to minimize the object. Furthermore, this will make it possible to minimize the object by double-clicking the caption.

- **Auto Minimize:** This option becomes available when **Allow Minimize** is checked. When **Auto Minimize** is checked for several sheet objects on the same sheet, all but one will be automatically minimized at any time. This is useful e.g. for alternately displaying several graphs in the same sheet area.
- **Allow Minimize:** When this option has been checked a maximize icon will be displayed in the window caption of the sheet object, providing that it is possible to maximize the object. Furthermore, this will make it possible to maximizing the object by double-clicking the caption. If both **Allow Minimize** and **Allow Maximize** are checked, double-clicking will effect minimizing of the object.
- **Help Text:** Here you may enter a help text to be displayed in a pop-up window. This option is not available at document level. The value may be entered as a calculated formula. Click  to open the **Edit Expression** dialog.  
It is possible to enter e.g. a description of the sheet object. A help icon will be added to the window caption of the object. When the mouse pointer is over the icon, the text will be displayed in a pop-up window.
- **Fast Type Change:** Here you can enable toggling between chart types. Not available for all objects.  
Click  to open the popup.
- **Fast Type Settings Popup:** Check the boxes for the chart types you want to toggle between using fast type change.

## Straight Table Properties: Options

### Options

Some options may not be available for all objects.

- **Read Only:** Makes the chart read only, that is selections cannot be made by clicking or painting with the mouse in the chart.
- **Allow Move/Size:** If this option has been deselected it will be impossible to move or resize the sheet object.
- **Allow Copy/Clone:** If this option has been deselected it will be impossible to make a copy of the sheet object. This setting may not be handled by all clients.
- **Size Object to Data:** Normally the borders around all table sheet objects in QlikView will shrink when selections cause the size of the table to be less than allocated size for the sheet object. By deselecting this check box this automatic adjustment of size will be turned off leaving any surplus space blank.
- **Allow Show Info in Caption:** When the Info function is in use an info icon will be displayed in the window caption whenever a field value has information associated to it. If you don't want the info icon to be displayed in the caption, you can uncheck this option. Only available for list box, statistics box, multi box and input box.
- **Preserve Scroll Position:** When marking this check box and the corresponding one in the **User Preferences, Objects** dialog, QlikView will preserve the vertical scroll position when a selection in table objects has been made.
- **Use Show Condition:** The sheet object will be shown or hidden depending on a conditional expression which will be evaluated continuously depending on e.g. selections etc. The sheet object

will only be hidden when the condition returns **false**. The value may be entered as a calculated formula. Click *fx* to open the **Edit Expression** dialog.

- **Normal**: Specify the position of the object by setting **Left** and **Top** margins, and **Width** and **Height** of the object.
- **Minimized**: Specify the position of the minimized sheet object by setting **Left** and **Top** margins, and **Width** and **Height** of the minimized object.
- **More.../Less...**: The following options are available:
  - **Owner**: Domain and User Id of the owner.
  - **Share Object**: Enable to share objects with other users. Enabling this selection will enable the settings below.
  - **Share with**: Choose either **Share with everyone** or **Share by username**.
  - **Users (Domain\UserID)**: If **Share by username** is chosen a list with added users will be shown.

To add users click , a row is added, highlight the row to unlock it and edit the user information. To remove users click  after each user to be removed.

# 12 Frequently Asked Questions

## 12.1 Installation

Q: What are the requirements for installing QlikView?

For information, see the QlikView online help.

## 12.2 QlikView Documents

Q: How much RAM do I need? Is there a simple way to relate RAM requirements to data volume?

A: No, it depends on the data structure and the type of data. The more rows of data and the wider each record is in terms of number of fields the more RAM is needed. If a field contains many different distinct values more RAM is required than if the number of distinct values is low. Certain charts may demand a large portion of RAM while being calculated.

Q: What is the theoretical limit of document size in QlikView?

A: It is impossible to translate this limit to a certain number of records (see question above). Typically QlikView uses 3-4 times as much memory during script execution as when working in the layout.

Q: I have 2 GB of RAM available but my 1 GB document gives me an "Out of memory" error message when opening. What is wrong?

A: Each table in a QlikView document requires allocation of a contiguous chunk of memory. If memory is fragmented, e.g. by loaded dll's, the allocation will fail and a correct error message will be shown. This behavior may vary between different computers.

Q: How large can documents be that are actually run in QlikView by real users?

A: When QlikView is run on a PC with say 512MB of RAM a few million rows of typical transaction data can be handled. In large servers with QlikView and several Gigabytes of RAM up to one billion rows (full transaction detail level without aggregation) are handled in customer applications at the time of writing (this information from May 2008 is 7 years old).

## 12.3 Scripts and Loading Data

Q: Is it possible to use more than one Binary statement in a QlikView script?

## 12 Frequently Asked Questions

---

A: No, unfortunately not. Binary load uses very special logic to read the data already processed once into QlikView in another QlikView document. The "unpacking" used requires a "clean slate" in memory which is the reason why a Binary statement must be the very first statement in the script. Therefore it is also impossible to use Binary more than once in a script. However you can use QVD files to consolidate data from multiple QlikView documents at the same speed as with Binary.

Q: Is the only requirement for an automatic join that the field names are the same?

A: Yes! Such a join is called an association.

Q: Can I achieve an automatic join between two fields with different field names?

A: Yes, but you must rename one of the fields in the script using an ALIAS statement or an AS clause.

*Renaming fields (page 172)*

Q: Can I use Where clauses, Group by clauses and other SQL-like syntax on text files?

A: QlikView offers you a rich script language for text files including large parts of SQL syntax and a number of additional features.

Q: Can I use Where clauses, Group By clauses and other SQL-like syntax on binary QlikView files?

A: No.

Q: What is the difference between an association between internal tables, a load or select statement preceded by a join qualifier, and a join within a select statement?

A: An association is a join between internal tables which is evaluated when you click on a field value in your document. QlikView makes this association automatically when two different tables have a field in common. The two latter joins are made during script execution and result in new logical tables. In these cases, QlikView does not load the original tables as logical tables.

Furthermore, a join within a select statement will usually only load those records whose key field value is found in both tables (inner join), whereas the two former joins also include records whose key field value is found in only one of the tables (full outer join).

Q: How do I load data from fix-record text files?

A: Use the table file wizard in QlikView.

*File Wizard: Type (page 100) and File Wizard: Type - Fixed Record (page 101)*

Q: Can I update a QlikView document by loading only the data that have changed?

A: Yes, using incremental reloads.

*QVD files (page 186)*

Q: Can I read tables from web pages into QlikView?

A: Yes, the table file wizard makes it possible to extract tables when they are coded as tables in HTML. If the HTML page does not contain nicely formatted table tags it is still usually quite possible to extract data using e.g. the subfield and textbetween script functions.

*File Wizard: Type - HTML (page 103)*

### 12.4 QlikView Logic

Q: Why is it impossible to show frequency in certain list boxes?

A: The list box in which this problem occurs contains a field which is common to more than one internal table. It is therefore impossible for QlikView to know how to calculate frequency and other statistical entities for the field. It is also possible to solve the problem by loading the field an extra time from its main table (the one for which you want to show frequency), but under a new name, and show frequency for that field within the list box instead. By using the label feature, the end user does not have to notice the trick.

Q: Why does my statistics box come up with just a lot of n/a?

A: The statistics box contains a field which is common to more than one internal table. See the answer to the previous question.

Q: Why doesn't QlikView allow me to use a certain field in an expression in a chart?

A: The field is common to more than one internal table. See the answer to the two previous questions.

Q: How can I display the number of distinct values in a statistics box?

A: Use the distinct clause in your load / select statements.

Q: When is the AND mode option in the List Box Properties dialog enabled?

A: The AND mode option is only allowed under very strict conditions, imposed by the theory behind the QlikView logic. In order to enable the AND mode, the field must:

- exist in only one internal table,
- be the second field of only two fields in that table and
- contain no duplicate records.
- it must be preceded by a distinct qualifier.

Q: Can I mix AND and OR logic for value selections within a list box?

A: No, the QlikView logic prohibits this.

Q: Can I have OR logic between list boxes?

A: Only indirectly. An advanced alternative is to use semantic links to transfer selections made in a list box to another field. Then change the selections in the original box and Ctrl-click on the semantic link to achieve OR between the two selections. The final result can be transferred by means of reversing the semantic link.

Q: Is it possible to link more than one info file to a value, e.g. a picture and a text file?

A: Yes, but only when duplicates of the field are used. Each field in QlikView can only be linked to one info file.

Q: Why are for instance '002', '02' and '2' sometimes interpreted as the same value by QlikView?

A: All the values in the example share the same numeric value in QlikView. As a rule, QlikView will try a numeric interpretation of any data. If a numeric interpretation is possible, it will be used for the association. If you use the interpretation function `text()` on a field in the script, however, the values will be treated strictly as text values. The values in the example above will then be interpreted as three different values.

Q: What is a "loop" or circular table structure?

A: When it is possible to follow the field associations in a never ending circle through the table structure, this is called a loop. Another way of describing the phenomenon is that there are two or more different routes through the table structure between two specific fields. Loops should be avoided as far as possible since they may cause ambiguities in the way data is interpreted. In many cases loops are a result of poor database design, but in other cases they may be unavoidable. QlikView will issue a warning if it finds a loop while executing the script and force you to resolve the problem with the help of loosely coupled tables.

*Understanding circular references (page 167)*

### 12.5 Layout

Q: Why can't sheet objects without caption be sized at its upper end?

## 12 Frequently Asked Questions

---

A: When you turn off the caption for a sheet object the upper border can only be used for moving the sheet object around, so instead use the upper corners of a sheet object to size.

Q: Why can't I expand my table to the right when I try to drag the border?

A: There are two handles on the right border of a table. If you drag the border of a table, you size the outer limits of what can be shown in the table. However, you can never make the outer frame larger than the sum of the widths of all columns in the table. The sizing of the rightmost column is made by putting the cursor just to the left of the outer border. Make sure that the outer frame does not fall in the middle of the column. If that is the case, use the scroll bar to position the column's right border at the outer frame. Use the design grid to see the actual outer frame of a sheet object.

Q: Can I change the name of a field in sheet objects in a QlikView document?

A: Yes, you can set a label for each field in each sheet object.

Q: Which sheet objects can be minimized?

A: All types of sheet objects can be minimized, but the option is set to off by default for sheet objects such as buttons, text objects and line/arrow objects.

Q: Can I move minimized objects on the sheet?

A: Yes, they can be moved freely and placed anywhere on the sheet and also sized within certain limits.

### 12.6 Sharing QlikView Documents with Other People

Q: Can I put my QlikView document on a server and share it with other people?

A: Yes, as long as the receivers have a registered QlikView license and access to the server directory.

Q: Can I use QlikView in real client/server mode?

A: Yes, you need a QlikView Server.

Q: Can I put my document as a link on a web page and let others access it over the net?

A: Yes, as long as the receivers have a registered QlikView license and access to the web page.

Q: Can I e-mail my document to other people?

## 12 Frequently Asked Questions

---

A: Yes, as long as the receivers have a registered QlikView license.

Q: Can I prevent certain people from using my document?

A: Yes, using "Section Access" to define who may use the document.

*Section (page 971) and Access Restriction Table Wizard (page 98)*

Q: Can I prevent other people from seeing/changing the script?

A: Yes, the "Section Access" can give some people ADMIN access level while keeping other people off the script in USER access level.

*Security (page 1588)*

Q: Where do I store information on access rights?

A: Information can be stored as a text file in a protected unit, or as a table in a database. It is also possible to store it as an inline statement in the script.

*Inline Data Wizard (page 97)*

Q: Is there an automated way to create personalized copies to a large group of users?

A: Yes, you need a QlikView Publisher which is an add-on module to QlikView Server.
